The balance, or **homeostasis**, of fluid, electrolytes, and acid–base is interrelated and maintained through the functions of almost every organ of the body. In a healthy person, fluid intake and fluid losses are about equal. Abnormalities in fluid, electrolyte, and acid–base balance are also interrelated and may occur together. This chapter provides information about principles of fluid, electrolyte, and acid–base balance and common disturbances. Sample interview questions for performing a fluid-balance assessment are included, with information on related physical assessment techniques and laboratory studies. Potential and actual health problems and needs are provided, and patient outcomes related to fluid and electrolyte balance are described. Appropriate nursing interventions include ongoing assessments, modifying dietary and fluid intake, administering medications, assisting with IV therapy, and blood replacement. The accompanying Concept Map on page 1714 and Evolving Case Study 41-1 on page 1728 provide opportunities to develop and apply clinical reasoning and clinical judgment skills.

Nurses combine knowledge of fluid, electrolyte, and acid–base balance with skilled nursing assessments and interventions to resolve alterations in health status and to improve patient outcomes. Refer to the accompanying Reflective Practice box.

PRINCIPLES OF FLUID, ELECTROLYTES, AND ACID–BASE BALANCE

Fluids and electrolytes are vital to life; adequate balance is imperative to maintain healthy functioning of the body. Fluids and electrolytes are involved in almost every cellular reaction and function. Chemical reactions that occur in the body depend on a regulated acid and base balance.

Body Fluids

The primary body fluid is water, making it the most important nutrient of life. Although life can be sustained for many days without food, humans can survive for only a few days without water. Water in the body functions primarily to:

- Transport nutrients to cells and wastes from cells
- Transport hormones, enzymes, blood platelets, and red and white blood cells
- Facilitate cellular metabolism and proper cellular chemical functioning
- Act as a solvent for electrolytes and nonelectrolytes
- Help maintain normal body temperature

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Facilitate digestion and promote elimination
- Act as a tissue lubricant

The term *total body water* or *fluid* refers to the total amount of water, which is approximately 50% to 60% of body weight in a healthy person (Brinkman et al., 2021).

Body Fluid Compartments

Body fluid is located in two fluid compartments—the intracellular fluid or extracellular fluid, based on its location in the body. **Intracellular fluid (ICF)** is the fluid within cells, constituting about 70% of the total body water or about 40% of the adult's body weight (Brinkman et al., 2021). **Extracellular fluid (ECF)** is all the fluid outside the cells, accounting for about 30% of the total body water or about 20% of the adult's body weight (Brinkman et al., 2021). ECF includes two major areas, the vascular (intravascular) and interstitial compartments. A third, usually minor, compartment is the transcellular fluid compartment. Intravascular fluid, or plasma, is the liquid component of the blood (i.e., fluid found within the vascular system). Interstitial fluid is the fluid that surrounds tissue cells and includes lymph (Hinkle et al., 2022). Transcellular fluids include cerebrospinal, pericardial, synovial, intraocular, and pleural fluids, as well as sweat and digestive secretions. The capillary walls and cell membranes separate the intracellular and extracellular compartments. Figure 41-1 illustrates the components of total body fluid and the primary fluid compartments.

QSEN Reflective Practice: Cultivating QSEN Competencies

CHALLENGE TO INTERPERSONAL SKILLS

During my clinical rotation in the emergency department, I met Grace Gilligan. She was a 28-year-old woman who came to the emergency department with severe episodes of nausea and vomiting over the last 48 hours. She has a past medical history of Crohn's disease, a GI problem for which she underwent bowel resection surgery 1 month ago. "I thought the surgery would help my problems." The patient was dehydrated and needed IV fluid therapy.

My coassigned nurse attempted to start a peripheral venous access not once, but six times. The patient was already upset by her recurrent abdominal symptoms, but now had to deal with the continuous painful stick of a needle. During the course of attempts to start the IV, the patient stated that a nurse on the IV team always had to be called to insert her IVs. Although my nurse acknowledged the information, she continued trying to start the IV. Finally, on the sixth try, as the patient was in tears, the nurse was successful. It seemed as if the nurse was out to prove her abilities without caring for the patient. By the end, I had difficulty even watching.

Thinking Outside the Box: Possible Courses of Action

- While assisting the nurse to obtain more supplies (outside the patient's room), mention to the nurse that maybe the use of ultrasound to guide placement and/or the IV team should be called (as the patient had requested), since "enough is enough!"
- Tell my clinical instructor that the patient is being abused.
- Ask the doctor if they could address the situation.
- Tell the patient when the nurse was out of the room to refuse any more sticks until the IV team was called.

Evaluating a Good Outcome: How Do I Define Success?

- Patient is benefited by my actions … or at least not harmed.
- All actions are supported by rationale.
- The patient's wishes are respected.
- Personal integrity is not compromised.

Personal Learning: Here's to the Future!

Unfortunately, I did not take any actions to protect this patient. This was my first time in the emergency department as well as my first introduction to the nurse. I was intimidated by her. Furthermore, I was scared when she continued to attempt the catheter insertion with the patient in tears. I know that it is my responsibility to advocate for the needs of my patients. In the future, I hope that I will never compromise my integrity, beliefs, and values to prove something to a student. If I fail or am not confident in my skills, I will admit this and stop before my patient is put at risk.

Amy Persinger, Georgetown University

QSEN SELF-REFLECTION ON QUALITY AND SAFETY COMPETENCIES DEVELOPING

KNOWLEDGE, SKILLS, AND ATTITUDES FOR CONTINUOUS IMPROVEMENT

How do you think you would respond in a similar situation? What does this tell you about yourself and about the adequacy of your skills for professional practice? Why? Do you agree with the criteria that the nursing student used to evaluate a successful outcome? Are there any other criteria that would be appropriate to use? Did the nursing student meet the criteria? Why or why not? What *knowledge, skills,* and *attitudes* do you need to develop to continuously improve the quality and safety of care for patients like Ms. Gilligan?

Patient-Centered Care: How could you involve Ms. Gilligan as a partner in coordinating her care to minimize frustration on the part of the patient, student, and nurse? What might have prompted the emergency department nurse to act as she did? The nursing student? How could the nursing student have advocated for the patient? What other barriers (other than those listed) might have interfered with the nursing student acting as an advocate?

Teamwork and Collaboration/Quality Improvement: What communication skills do you need to improve to ensure that you function as a member of the patient-care team? What skills do you need to implement effective strategies for communicating and resolving conflict? What skills do you need to assert your own position/perspective in discussions about patient care?

Safety/Evidence-Based Practice: What evidence for practice provides guidance for decision making regarding professional practice and venipuncture?

Informatics: Can you identify the essential information that must be available in Ms. Gilligan's electronic record to support safe patient care and coordination of care? Can you think of other ways to respond to or approach the situation?

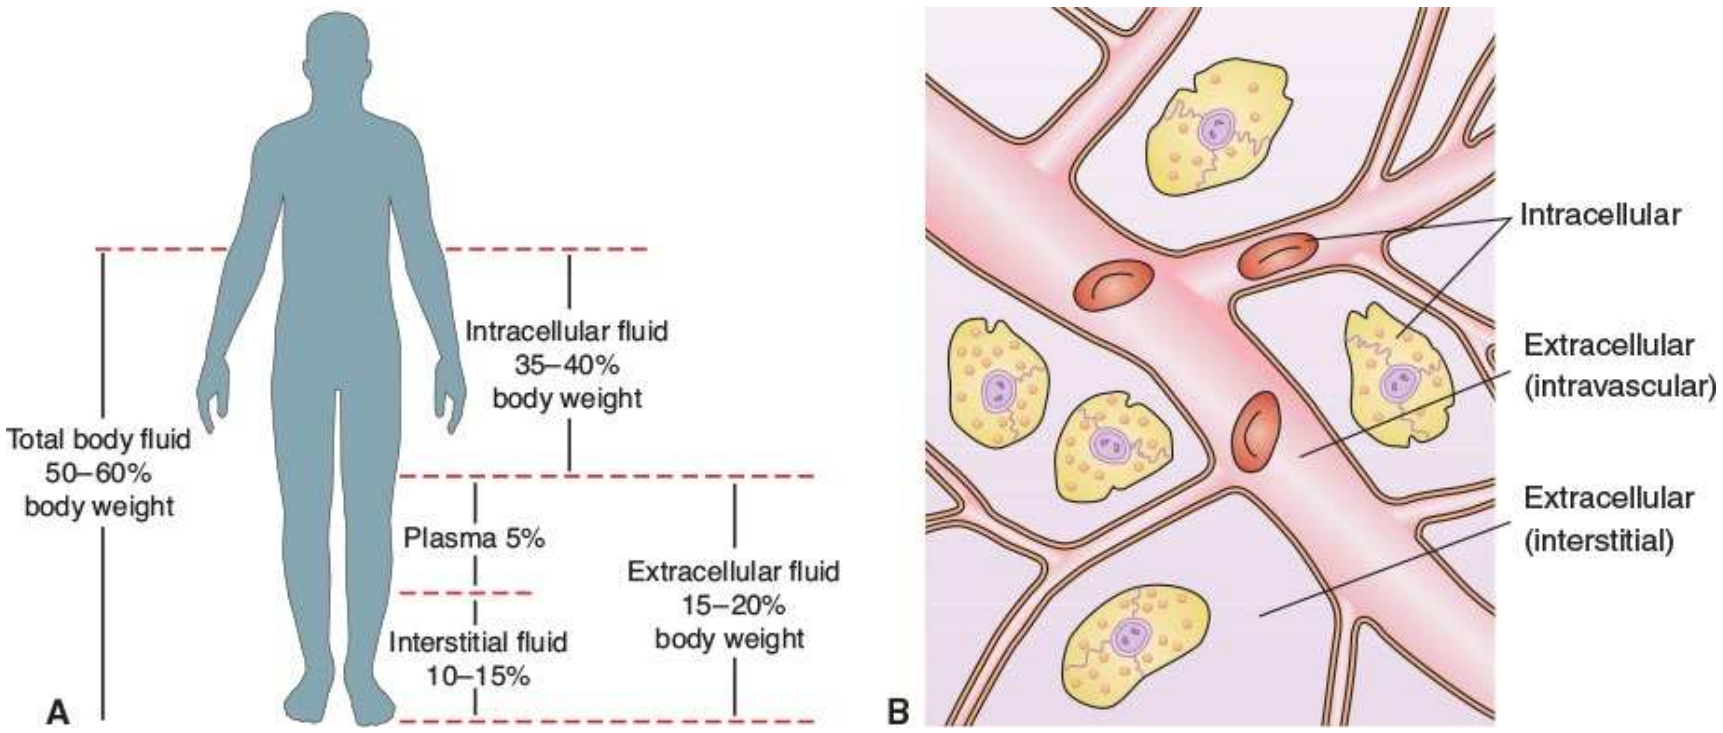

FIGURE 41-1. A. Total body fluid represents 50% to 60% of body weight of a normal adult. **B.** Primary fluid compartments.

Variations in Fluid Content

Variations in the fluid content from the normal 50% to 60% of the body's weight can occur, depending on such factors as the person's age, body fat, and biologic sex. Infants have considerably more total body fluid and ECF than adults. Because ECF is more easily lost from the body than ICF, infants are at increased risk for fluid volume deficits (FVDs).

Total body water also differs by biologic sex and the amount of fat cells in the body. Fat cells contain little water, whereas lean tissue is rich in water. Thus, the more obese a person is, the smaller the person's percentage of total body water is when compared with body weight. Because women tend to have proportionally more body fat than men do, they also have less body fluid than men.

Similarly, the decreasing percentage of body fluid in older people is related to an increase in fat cells. In addition, older adults lose muscle mass as a part of aging. The combined increase of fat and loss of muscle results in reduced total body water; after the age 60 years, total body water is about 45% of a person's body weight (Willis, 2020). This decrease in water increases the risk for fluid imbalance in older adults.

Fluid Balance

The human body obtains water from several sources, including ingested liquids, food, and as a byproduct of metabolism. The ingestion of liquids provides the largest amount of water normally taken into the body. Fluid intake is regulated

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

primarily by the thirst mechanism. Located within the hypothalamus, the thirst control center is stimulated by intracellular **dehydration** (the loss of or deprivation of water from the cells [Willis, 2020]) and decreased blood volume. The water contained in food is the second largest source of water for the body. The amount of water ingested depends on the person's dietary intake. For example, melons and citrus fruit are high in water content, whereas cereal and dried fruits have relatively low water content. Water is an end product of the oxidation that occurs during the metabolism of food substances, specifically carbohydrates, fats, and protein. This amount of water obtained varies among the different types of nutrients. In general, fluid intake averages 2,600 mL per day, with approximately 1,500 mL coming from ingested liquids; 800 mL coming from ingested food, and 300 mL from metabolic oxidation (Willis, 2020). Figure 41-2 illustrates daily fluid balance in a healthy person.

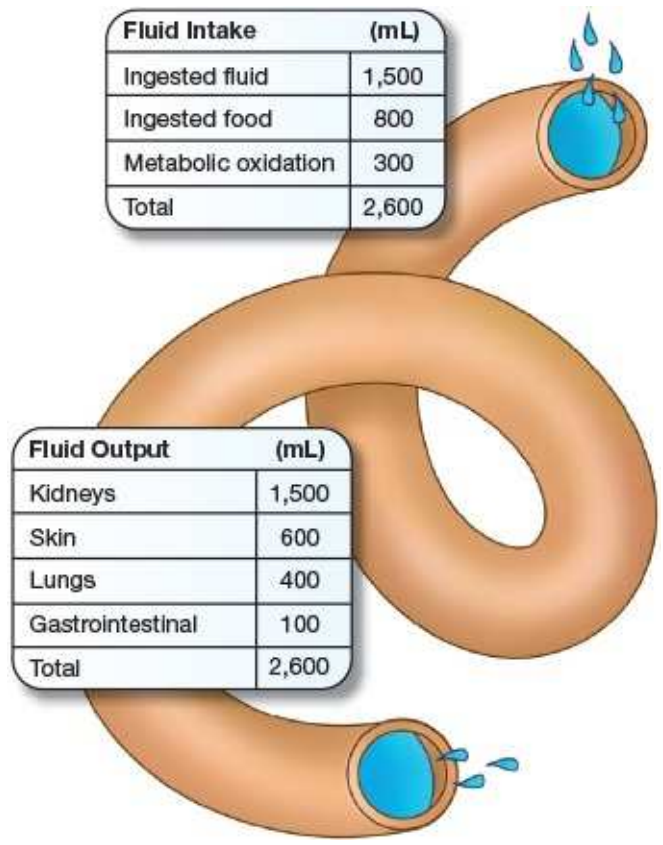

FIGURE 41-2. In health, fluid intake and fluid losses are about equal. The amounts indicated are average adult daily fluid sources and losses.

Fluid is lost from the body through *sensible* and *insensible* losses. Sensible losses can be measured and include fluid lost during urination, defecation, and wounds. Insensible losses cannot be measured or seen and include fluid lost from evaporation through the skin and as water vapor from the lungs during respiration. Water losses vary according to the person and the circumstances. Fluid output averages 2,600 mL per day, with approximately 1,500 mL as urine from the kidneys, 600 mL fluid loss from the skin, 400 mL from the lungs, and 100 mL in feces via the gastrointestinal (GI) tract (Willis, 2020) (see Fig. 41-2).

A person's health state as well as balance between actual fluid intake and loss must be considered when assessing nursing needs. A person's intake should normally be approximately balanced by output or fluid loss. A general rule is that in healthy adults, the output of urine normally approximates the ingestion of liquids, and the water from food and oxidation is balanced by the water loss through the feces, the skin, and the respiratory process. The intake–output balance may not always occur in a single 24-hour period but should normally be achieved within 2 to 3 days.

Consider **Jeremiah Stein**, the young student experiencing loose bowel movements for a week. Jeremiah is at increased risk for fluid imbalance related to the increased loss of water via the GI tract. It would be important for the nurse in the health center to teach Jeremiah about the need to increase their fluid intake to compensate for the extra losses.

Any deviations from normal ranges for a balanced water intake and output should alert the nurse to potential imbalances. The accompanying Promoting Health 4-1 display reflects on self-care behaviors vital for maintaining a healthy fluid and electrolyte balance. Nurses who role model good health behaviors are more effective teachers. Use the Promoting Health display for yourself before using it with others.

Electrolytes

Electrolytes are substances that are capable of breaking into particles called ions. An **ion** is an atom or molecule carrying an electrical charge. Some ions develop a positive charge and are called **cations**. The major cations in body fluid are sodium, potassium, calcium, hydrogen, and magnesium. Other ions develop a negative charge and are called **anions**. The major anions in body fluid are chloride, bicarbonate, and phosphate. These charged particles are the basis of chemical interactions in the body necessary for metabolism and other functions. Molecules in the body that remain intact, without a charge, are called nonelectrolytes. In the human body, urea and glucose are examples of nonelectrolytes.

The electrolyte content of the fluids in various compartments of the body differs significantly. Major electrolytes in the ECF include sodium, chloride, calcium, and bicarbonate. Major electrolytes in the ICF include potassium, phosphorus, and magnesium. The functions, sources, means of loss, and regulation of these electrolytes are highlighted in Table 41-1; hydrogen is discussed as part of acid–base balance. Figure 41-3 (on page 1674) illustrates differences in the electrolyte composition of body fluids according to the compartments in which the fluids are found.

Promoting Health 41-1

FLUID AND ELECTROLYTE BALANCE

Use the assessment checklist to determine how well you are meeting your fluid and electrolyte needs. Then develop a prescription for self-care by choosing appropriate behaviors from the list of suggestions.

Assessment Checklist

☐ almost always ☐ sometimes ☐ almost never

☐	☐	☐	1. I drink six to eight glasses of water every day.
☐	☐	☐	2. I am aware of early signs of excess fluid volume loss or fluid volume retention.
☐	☐	☐	3. I limit sugar, alcohol, and caffeine in my diet.
☐	☐	☐	4. I am alert for any sudden variations in my weight.
☐	☐	☐	5. I am aware of fluid and electrolyte imbalances that may be associated with intake of certain medications
☐	☐	☐	6. I diet sensibly when I need to lose weight.

Self-Care Behaviors

1. Consume about 1½ quarts of water daily.
2. Maintain normal body weight.
3. Avoid consuming excess amounts of products high in salt, sugar, and caffeine.
4. Limit alcohol intake because of its diuretic effect.
5. Obtain medical evaluation for any ongoing indications of fluid imbalance.
6. Monitor side effects of medications, especially diuresis and diarrhea.
7. Identify situations of high risk for fluid and electrolyte imbalance and intervene appropriately.

Information to promote fluid and electrolyte balance is available online.

Table 41-1 Major Electrolytes

ELECTROLYTE	FUNCTIONS	SOURCES AND LOSSES	REGULATION
Sodium (Na^+): chief electrolyte of ECF; normal serum concentration of sodium: 135–145 mEq/L	Regulates extracellular fluid volume; Na^+ loss or gain accompanied by a loss or gain of water Affects serum osmolality Role in muscle contraction and transmission of nerve impulses Regulation of acid–base balance as sodium bicarbonate	Normally enters the body through the gastrointestinal tract from dietary sources, such as salt added to processed foods, sodium preservatives added to processed foods Lost from GI tract, kidneys, and skin	Transported out of the cell by the sodium-potassium pump Regulated by renin–angiotensin–aldosterone system Elimination and reabsorption regulated by the kidneys Sodium concentrations affected by salt and water

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

			intake
Potassium (K^+): major cation of ICF; normal serum concentration of potassium: 3.5–5.0 mEq/L	Controls intracellular osmolality Regulator of cellular enzyme activity Role in the transmission of electrical impulses in nerve, heart, skeletal, intestinal, and lung tissue; Regulation of acid–base balance by cellular exchange with H^+	Adequate quantities via a well-balanced diet Leading food sources: fruits and vegetables, dried peas and beans, whole grains, milk, meats Lost via kidneys, stool, sweat, emesis	Regulated by aldosterone Eliminated by the kidneys (no effective method of conserving potassium) Additional regulation via transcellular shift between the ICF and ECF compartments
Calcium (Ca^{2+}): most abundant electrolyte in the body; normal total serum calcium level: 8.6–10.2 mg/dL; normal ionized serum calcium level: 4.5–5.1 mg/dL	Role in blood coagulation and in transmission of nerve impulses Helps regulate muscle contraction and relaxation Major component of bones and teeth	Absorbed from foods in the presence of normal gastric acidity and vitamin D Lost via feces and urine Sources include milk and milk products; dried beans; green, leafy vegetables; small fish with bones; and dried peas and beans	Primarily excreted by GI tract; lesser extent by kidneys Regulated by parathyroid hormone and calcitonin High serum phosphate results in decreased serum calcium; low serum phosphate leads to increased serum calcium
Magnesium (Mg^{2+}): second most abundant ICF cation after potassium; normal serum concentration of magnesium: 1.3–2.3 mEq/L	Metabolism of carbohydrates and proteins Role in neuromuscular function Acts on cardiovascular system, producing vasodilation	Enters the body via GI tract Sources include green, leafy vegetables; nuts; seafood; whole grains; dried peas and beans; cocoa Lost via urine with use of loop diuretics	Eliminated by kidneys Regulated by parathyroid hormone
Chloride (Cl^-): major ECF anion; normal serum level of chloride: 97–107 mEq/L	Major component of interstitial and lymph fluid; gastric and pancreatic juices, sweat, bile, and saliva Acts with sodium to maintain the osmotic pressure Combines with hydrogen ions to produce hydrochloric acid	Enters body via GI tract Almost all chloride in diet comes from salt Found in foods high in sodium, processed foods	Normally paired with sodium; excreted and conserved with sodium by the kidneys Regulated by aldosterone Low potassium level leads to low chloride level
Bicarbonate (HCO_3^-): an anion that is the major chemical base buffer within the body; found in both ECF and ICF; normal serum bicarbonate level: 25–29 mEq/L	Regulates acid–base balance	Losses possible via diarrhea, diuretics, and early renal insufficiency Excess possible via overingestion of acid neutralizers, such as sodium bicarbonate	Bicarbonate levels regulated primarily by the kidneys Bicarbonate readily available as a result of carbon dioxide formation during metabolism
Phosphate (PO_4^-): major ICF anion;	Role in acid–base balance as a hydrogen buffer	Enters body via GI tract Sources include all animal	Eliminated by kidneys Regulation by parathyroid

a buffer anion in both ICF and ECF; normal serum phosphate level: 2.5–4.5 mg/dL	Promotes energy storage; carbohydrate, protein, and fat metabolism Bone and teeth formation Role in muscle and red blood cell function	products (meat, poultry, eggs, milk, bread, ready-to-eat cereal) Absorption is diminished by concurrent ingestion of calcium, magnesium, and aluminum	hormone and by activated vitamin D Phosphate and calcium are inversely proportional; an increase in one results in a decrease in the other

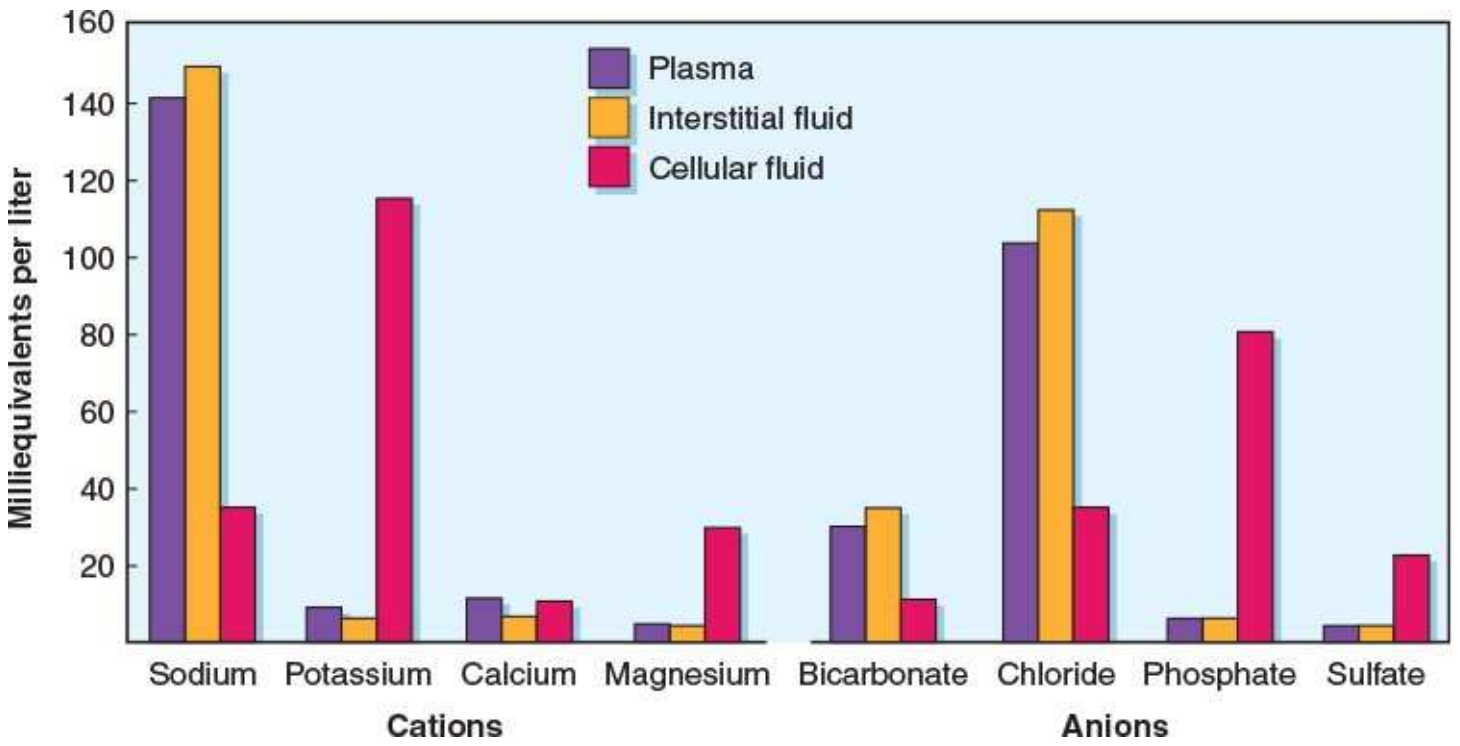

FIGURE 41-3. Electrolyte composition of body fluids according to compartment.

Electrolytes are measured in terms of their chemical combining power, or chemical activity. The milliequivalent (mEq) is the unit of measure that describes the chemical activity of electrolytes. One milliequivalent of either a cation or an anion is chemically equivalent to the activity of 1 mg of hydrogen. Therefore, 1 mEq of any cation is equivalent to 1 mEq of any anion. The total cations in the body are normally equal to the total anions, maintaining homeostasis (balanced state). In healthy people, the milliequivalents per liter for electrolytes in the body vary within a relatively narrow range. When electrolytes are not in balance, the person is at risk for alterations in health.

Consider **Grace Gilligan**, the young female described in one of the beginning chapter scenarios. The nurse would need to be alert for electrolyte imbalances and possible acid–base imbalance due to the loss of gastric secretions from vomiting.

Regulation and Homeostatic Mechanisms of Fluid and Electrolyte Balance

Maintaining homeostasis of fluid volume and electrolytes is essential to healthy body functioning. Fluid and electrolyte homeostasis normally functions automatically and effectively.

Fluid and electrolyte balance is maintained by a number of mechanisms to facilitate fluid and electrolyte movement within the body. **Solvents** are liquids that hold a substance in solution; **solutes** are substances that are dissolved in a solution. Water is the primary solvent in the body. The solutes are electrolytes and nonelectrolytes. The body produces balance by shifting fluids and solutes between the ECF and the ICF. The mechanisms responsible for regulating this shift of fluids and transporting materials to and from intracellular compartments include organs and body systems, osmosis, diffusion, active transport, and capillary filtration, and are described in the following sections.

Organs and Body Systems

Almost every organ and system in the body helps in some way to maintain fluid homeostasis. The specific functions of these organs and body systems related to the regulation of fluid and electrolyte balance are highlighted in Table 41-2.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Osmosis

Cell membranes are semipermeable, allowing some, but not all, solutes to pass through the cell membranes. The cell membrane is permeable to water or fluids. Through the process of **osmosis**, water (the solvent) passes from an area of lesser solute concentration and more water to an area of greater solute concentration and less water until equilibrium is established. As a result, the volume of the more concentrated solution increases, and the volume of the weaker solution decreases. The process of osmosis stops when the concentration of solutes has been equalized on both sides of the cell membrane. The greater the difference in the concentration of the two solutions on each side of a semipermeable membrane, the greater the osmotic pressure of water. Osmosis is the major method of transporting body fluids. Water shifts and balance depend heavily on this route of transport, illustrated in Figure 41-4 on page 1676.

The concentration (number) of particles dissolved in a solution is referred to as the **osmolality** of a solution, which influences the movement of fluid between compartments (Hinkle et al., 2022). A solution that has about the same osmolality as plasma (280 mOsm/L) is considered an isotonic solution (Norris, 2020). An **isotonic** fluid remains in the intravascular compartment without any net flow across the semipermeable membrane. In contrast, a **hypertonic solution** has a greater osmolality than. Because a hypertonic solution has a greater osmolality, water moves out of the cells and is drawn into the intravascular compartment, causing the cells to shrink. A **hypotonic solution** has less osmolality than plasma. Because of a lower osmolality, a hypotonic solution in the intravascular space moves out of the intravascular space and into ICF, causing cells to swell and possibly burst.

Diffusion

Diffusion is the tendency of solutes to move freely throughout a solvent. The solute moves from an area of higher concentration to an area of lower concentration until equilibrium is established. Figure 41-5 illustrates this mechanism. Gases also move by diffusion. Oxygen and carbon dioxide exchange in the lung's alveoli and capillaries occurs by diffusion.

Table 41-2 Organs and Body Systems Related to the Regulation of Fluid, Electrolyte, and Acid–Base Balance

ORGAN/BODY SYSTEM	FUNCTIONS
Kidneys	• Regulate extracellular fluid (ECF) volume and osmolality by selective retention and excretion of body fluids • Regulate electrolyte levels in the ECF by selective retention of needed substances and excretion of unneeded substances • Regulate pH of ECF by excretion or retention of hydrogen ions • Excrete metabolic wastes (primarily acids) and toxic substances • Normally filter 180 L of blood daily in the adult, while excreting only 1–2 L of urine per day
Heart and blood vessels	• Circulate nutrients and water throughout the body • Circulate blood through the kidneys under sufficient pressure for urine to form (pumping action of the heart) • React to hypovolemia by stimulating fluid retention (stretch receptors in the atria and blood vessels)
Lungs	• Remove approximately 300 mL of water daily through exhalation (insensible water loss) in the normal adult • Eliminate about 13,000 mEq of hydrogen ions (H^+) daily, as opposed to only 40–80 mEq excreted daily by the kidneys • Act promptly to correct metabolic acid–base disturbances; regulate H^+ concentration (pH) by controlling the level of carbon dioxide (CO_2) in the extracellular fluid
Adrenal glands	• Regulate blood volume and sodium and potassium balance by

	secreting aldosterone, a mineral corticoid secreted by the adrenal cortex, causing sodium retention (and thus water retention) and potassium loss. • Decreased secretion of aldosterone causes sodium and water loss and potassium retention. • Cortisol, another adrenocortical hormone, has only a fraction of the potency of aldosterone. However, secretion of cortisol in large quantities can produce sodium and water retention and potassium deficit.
Pituitary gland	• Stores and releases the antidiuretic hormone (ADH) (manufactured in the hypothalamus), which acts to allow the body to retain water. It acts chiefly to regulate sodium and water intake and excretion. • When osmotic pressure of the ECF is greater than that of the cells (as in hypernatremia—excess sodium—or hyperglycemia), ADH secretion is increased, causing renal retention of water. • When osmotic pressure of the ECF is less than that of the cells (as in hyponatremia), ADH secretion is decreased, causing renal excretion of water. • When blood volume is decreased, an increased secretion of ADH results in water conservation. • When blood volume is increased, a decreased secretion of ADH results in water loss.
Thyroid gland	• Increases blood flow in the body by releasing thyroxine, leading to increased renal circulation and resulting in increased glomerular filtration and urinary output.
Nervous system	• Inhibits and stimulates mechanisms influencing fluid balance; acts chiefly to regulate sodium and water intake and excretion • Regulates oral intake by sensing intracellular dehydration, which triggers thirst (thirst center located in the hypothalamus) • Neurons, called osmoreceptors, are sensitive to changes in the concentration of ECF, sending appropriate impulses to the pituitary gland to release ADH or inhibit its release to maintain ECF volume concentration.
Gastrointestinal tract	Absorbs water and nutrients that enter the body through this route.
Parathyroid glands	• Regulate calcium (Ca^{2+}) and phosphate (HPO_4^{2-}) balance by means of parathyroid hormone (PTH); PTH influences bone reabsorption, calcium absorption from the intestines, and calcium reabsorption from the renal tubules. • Increased secretion of PTH causes elevated serum calcium concentration and lowered serum phosphate concentration. • Decreased secretion of PTH causes lowered serum calcium concentration and elevated serum phosphate concentration.

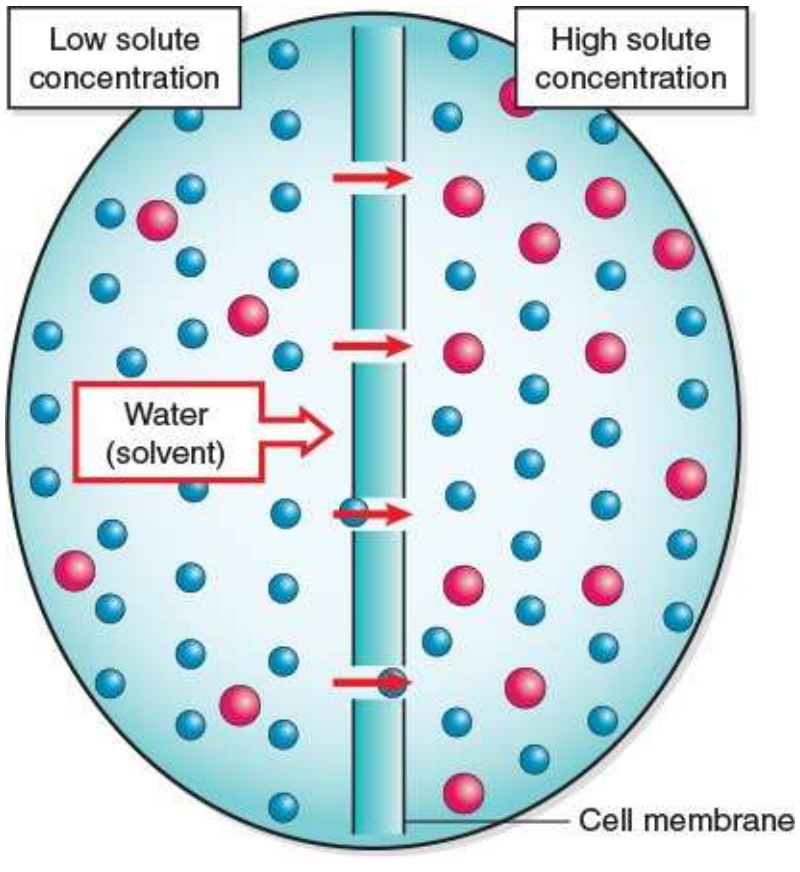

FIGURE 41-4. Osmosis. Body fluids are transported through cell membranes through the process of osmosis. Water, a solvent, moves from an area of lesser solute concentration to one of greater solute concentration, until equilibrium is established.

Active Transport

Active transport is a process that requires energy for the movement of substances through a cell membrane, against the concentration gradient, from an area of lesser solute concentration to an area of higher solute concentration. Adenosine triphosphate (ATP), which is stored in all cells, supplies energy for solute movement in and out of the cell. Although this process is not entirely understood, the energy requirements for active transport are affected by characteristics of the cell membrane, specific enzymes, and concentrations of ions. This process explains the so-called pump mechanism, illustrated in Figure 41-6. Substances that require active transport to cross cell membranes include amino acids, glucose (in certain places only, such as in the kidneys and intestines), and ions of sodium, potassium, hydrogen, and calcium (Willis, 2020).

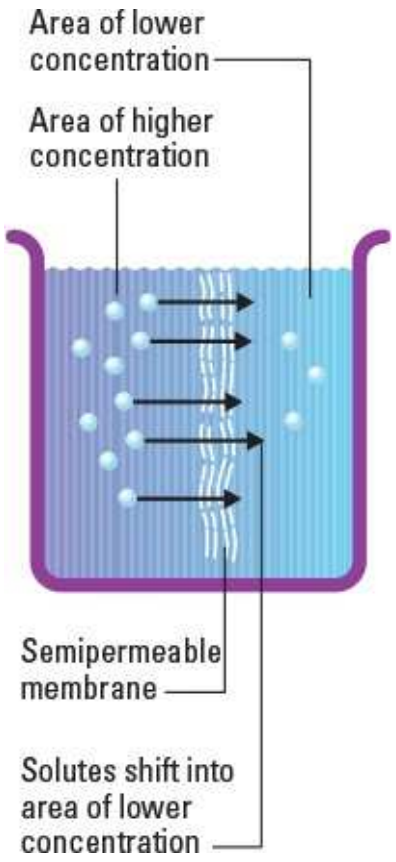

FIGURE 41-5. Diffusion. Solutes move from an area of higher concentration to an area of lower concentration until the concentration is equal in both areas.

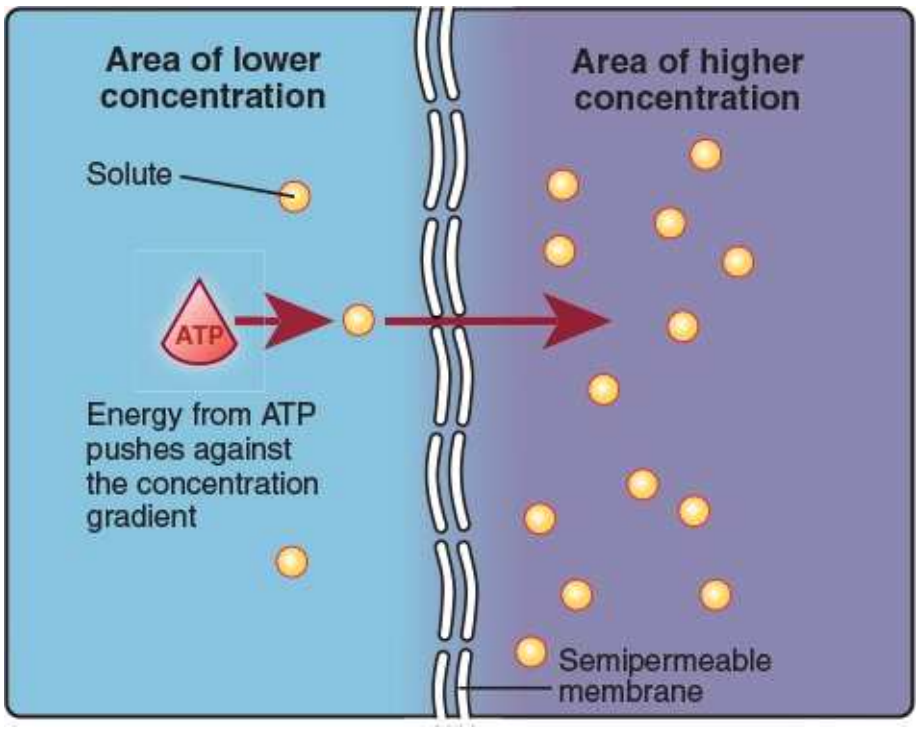

FIGURE 41-6. Active transport. Solutes are moved from an area of lower concentration to an area of higher concentration.

Capillary Filtration

Filtration is the passage of fluid through a permeable membrane. Fluids move from an area of high pressure to one of lower pressure. **Capillary filtration** results from the force of blood "pushing" against the walls of the capillaries. At the arterial end of the capillaries, filtration is dependent primarily on arterial blood pressure; at the venular side of the capillaries, filtration is dependent on venous blood pressure. The "pushing" force is referred to as **hydrostatic pressure**. When the hydrostatic pressure inside the capillary exceeds the surrounding interstitial space, fluids and solutes are forced out of the capillary wall into the interstitial space. In contrast, when the pressure inside the capillary is less than the pressure in the interstitial space, the fluids and solutes will move back into the capillary.

Reabsorption is the process that acts to prevent too much fluid from leaving the capillaries no matter how high the hydrostatic pressure. Plasma proteins, particularly albumin, concentrated in the intravascular space or plasma facilitate this reabsorption process by "pulling" the fluid back into the capillaries. This "pulling" force is known as **colloid osmotic pressure**, or oncotic pressure. Under normal conditions, hydrostatic pressure in the arteriole end of a capillary exceeds plasma colloid pressure. Hydrostatic pressure at the venule end of the capillary is less than plasma colloid pressure. As a result, capillary filtration occurs along the first half of the vessel, and reabsorption occurs along the second half. Filtration pressure is the difference between colloid osmotic pressure and blood hydrostatic pressure.

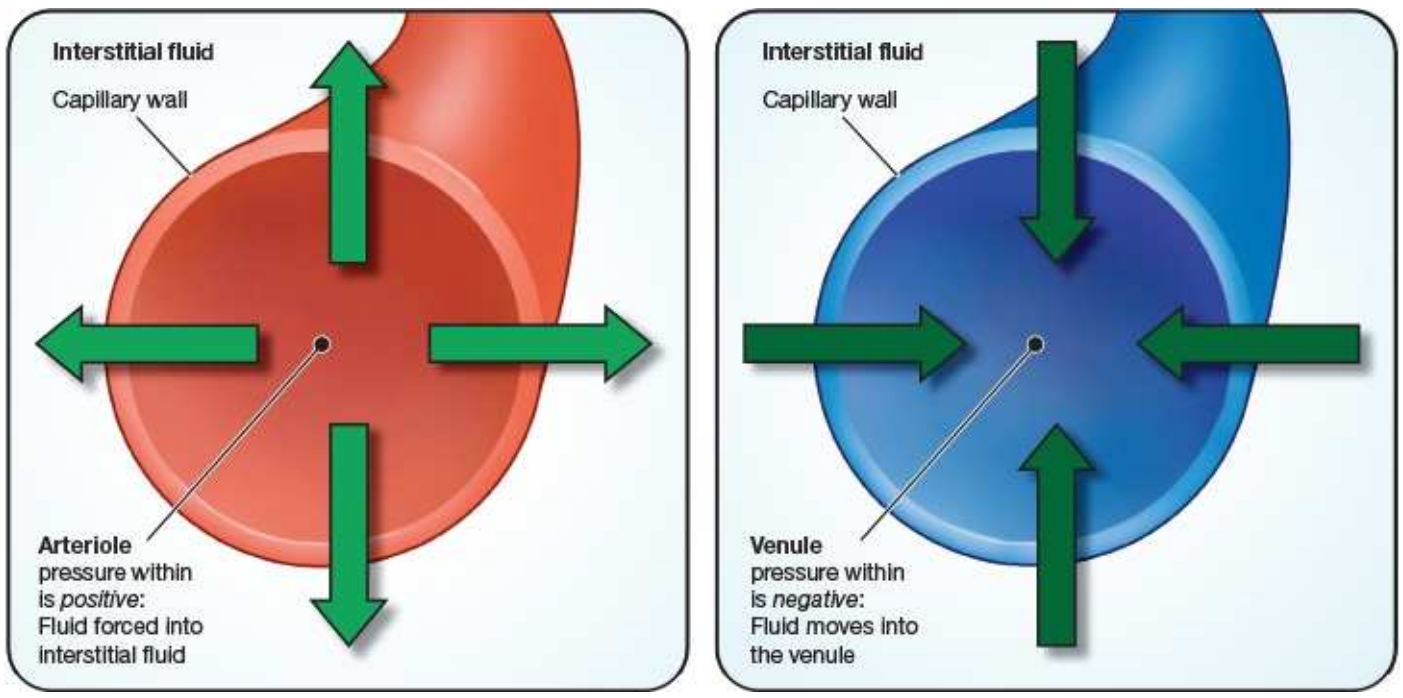

FIGURE 41-7. Capillary filtration.

These pressures are important in understanding how fluid leaves arterioles, enters the interstitial compartment, and eventually returns to the venules. The filtration pressure is positive in the arterioles, helping to force or filter fluids into interstitial spaces; it is negative in the venules and thus helps fluid enter the venules (refer to Fig. 41-7). Filtration is also involved in the proper functioning of the glomeruli of the kidneys.

Acid–Base Balance

Body fluids must maintain an acid–base balance to sustain health, homeostasis, and life. Specific chemical reactions are constantly occurring within the body that influence metabolism and the functions of various bodily systems. These chemical reactions are dependent on a balance of acids and bases. Changes in health such as infection or trauma may alter this delicate acid–base balance. Acidity or alkalinity of a solution is determined by its concentration of hydrogen

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

ions (H^+). An **acid** is a substance containing H^+ that can be liberated or released, such as carbonic acid. An alkali, or **base**, is a substance that can accept or trap H^+ ions, such as the bicarbonate ion.

An acid releases H^+, as follows:

$$\underset{\text{carbonic acid}}{H_2CO_3} \xrightarrow{\text{releases}} \underset{\text{hydrogen ion}}{H^+} + \text{to form} \; \underset{\text{bicarbonate base}}{HCO^-_3}$$

A base traps H^+, as follows:

$$\underset{\text{bicarbonate base}}{HCO^-_3} + \underset{\text{hydrogen ion}}{H^+} \xrightarrow{\text{to form}} \underset{\text{carbonic acid}}{H_2CO_3}$$

A strong acid dissociates (separates) completely in solution and releases all of its H^+ ions, whereas a weak acid releases only a small number. A base that binds or accepts H^+ ions easily is considered a strong base, whereas one that accepts H^+ ions less readily is considered weak.

The unit of measure used to describe acid–base balance is **pH**, which is an expression of H^+ ion concentration and the resulting acidity or alkalinity of a substance. The pH scale ranges from 1 to 14. A neutral solution measures 7; an example of a neutral solution is pure water. Because pH is based on a negative logarithm, as the H^+ ions increase and a solution becomes more acid, the pH becomes less than 7. When the concentration of H^+ ions in a solution is reduced or accepted by another substance and the solution contains more base than acid, it is alkaline, and the pH is greater than 7. Gastric secretions that are strongly acidic have an approximate pH of 1 to 1.3, whereas strongly alkaline pancreatic secretions have an approximate pH of 10.

Normal blood plasma is slightly alkaline and has a normal pH range of 7.35 to 7.45 (Norris, 2020). When the blood plasma pH exceeds the normal pH range in either direction, signs and symptoms of illness develop, and if the condition goes on unabated, death results. **Acidosis** is the condition characterized by an excess of H ions or loss of base ions (bicarbonate) in ECF in which the pH falls below 7.35 (Willis, 2020). **Alkalosis** occurs when there is a loss of H ions or a gain of bases (e.g., bicarbonate) and the pH exceeds 7.45 (Willis, 2020). Refer to the Acid–Base Imbalances discussion on page 1681. Figure 41-8 illustrates normal pH, acidosis, and alkalosis and shows the points at which death typically occurs. The narrow range of normal pH is achieved through three major homeostatic regulators of hydrogen ions: (1) chemical buffer systems, (2) respiratory mechanisms, and (3) renal mechanisms. There are alterations in these systems related to the developmental stage of an individual. Newborns are not able to acidify urine as well as adults (Willis, 2020). As people age, the effectiveness of both the lungs and kidneys can vary. In an older adult, if there is underlying lung disease, the regulation of acid–base balance may be less efficient. In addition, the kidneys of the older adult can have difficulty handling excess amounts of acid (Willis, 2020).

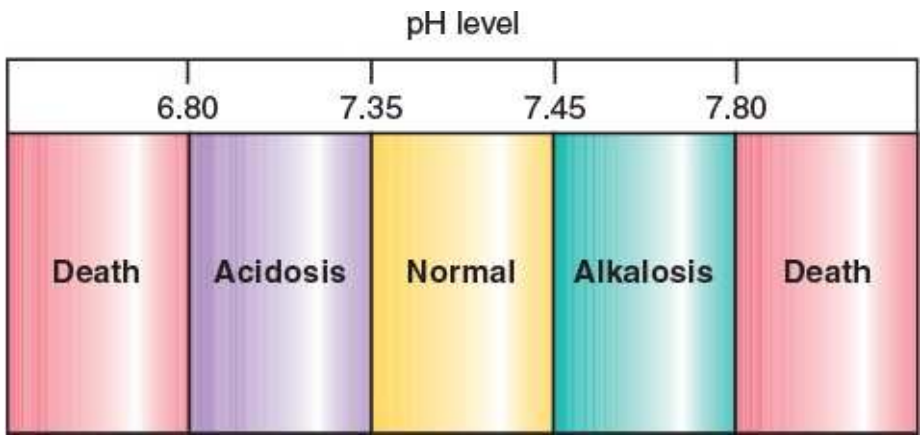

FIGURE 41-8. Acid–base balance. Note that acidosis is used to describe the condition of the pH falling below 7.35, and alkalosis describes a pH above 7.45. When the normal pH is exceeded in either direction, death can occur.

Chemical Buffer Systems

A **buffer** is a substance that prevents body fluids from becoming overly acidic or alkaline. Buffers combine with excess acids or bases to prevent major changes in pH, keeping the pH of body fluids as close as possible to normal. Buffers work in one of two ways. A buffer can function like a base and bind or soak up free hydrogen ions. Alternatively, it may function like an acid and release hydrogen ions when too few are present in a solution. The body has three chemical buffer systems: (1) the carbonic acid–sodium bicarbonate buffer system, (2) the phosphate buffer system, and (3) the protein buffer system.

CARBONIC ACID–SODIUM BICARBONATE BUFFER SYSTEM

The ratio of carbonic acid (H_2CO_3), the most common acid in human body fluid, to the body's most common base, bicarbonate (HCO_3^-), is important for acid–base balance and is the most important buffer system of the body. Normal ECF has a ratio of 20 parts bicarbonate to 1 part carbonic acid (Hinkle et al., 2022). The exact quantities are unimportant for acid–base balance as long as they remain in a 20:1 ratio. Carbonic acid and bicarbonate must be carefully controlled to maintain this ratio; if either is increased or decreased, the 20:1 ratio is no longer in effect and pH will change (Norris, 2020). The lungs help by regulating the production of carbonic acid resulting from the combination of carbon dioxide

and water. The kidneys assist the bicarbonate system by regulating the production of bicarbonate.

PHOSPHATE BUFFER SYSTEM

The phosphate buffer system is active in ICFs, especially in the renal tubules. Phosphate buffers react with either acids or bases to form compounds that slightly alter pH to provide effective buffering (Willis, 2020).

PROTEIN BUFFER SYSTEM

The third buffer system is a mixture of plasma proteins and the globin portion of hemoglobin in red blood cells. Because plasma proteins and hemoglobin possess chemical groups that can combine with or liberate hydrogen ions, they tend to minimize changes in pH and serve as excellent buffering agents over a wide range of pH values working both inside and outside the cells (Willis, 2020). For example, excess hydrogen ions in the blood cross over the plasma membrane of red blood cells and bind to the hemoglobin molecules that are plentiful in each red blood cell.

Respiratory Regulation of Hydrogen Ions

Due to the huge surface area from which CO_2 can readily diffuse, the lungs can bring about rapid changes in H^+ when needed. Carbon dioxide, constantly produced by cellular metabolism (carbonic acid [H_2CO_3] yields CO_2 and H_2O), is excreted by exhalation. When the amount of CO_2 in the blood increases, the sensitive chemoreceptors in the respiratory center in the medulla and in the carotid and aortic bodies are stimulated to increase the rate and depth of respirations to eliminate more CO_2. As more CO_2 is exhaled, the H_2CO_3 level in the blood decreases, and the pH of the blood becomes more alkaline. When the blood level of CO_2 decreases, the respiratory center decreases the rate and depth of respirations to retain the CO_2 so that carbonic acid can be formed, thereby maintaining the delicate balance. As a result, the lungs are the primary controller of the body's carbonic acid supply. This total respiratory process occurs almost as rapidly as the buffering action in the carbonic acid–sodium bicarbonate system. The respiratory system is able to respond quickly in a healthy individual to restore the normal pH. However, this response is short term, and the response of the kidneys is needed for long-term adjustment (Willis, 2020).

Renal Regulation of Hydrogen Ions

Essentially, the kidneys excrete or retain hydrogen ions and form or excrete bicarbonate ions in response to the pH of the blood. In the presence of acidosis, the kidneys excrete hydrogen ions and form and conserve bicarbonate ions, thus raising the pH to the normal range. If alkalosis is present, the kidneys retain hydrogen ions and excrete bicarbonate ions in an effort to return to a balanced state. As a result, the concentration of bicarbonate in the plasma is regulated by the kidneys.

Acid–base regulation by the kidneys occurs more slowly than that which occurs by the carbonic acid–sodium bicarbonate system or by respiratory regulation. It may take as long as 3 days for a normal fluid pH to be restored by the kidneys.

DISTURBANCES IN FLUID, ELECTROLYTE, AND ACID–BASE BALANCE

Nurses may encounter actual and potential disturbances in fluid, electrolyte, and acid–base balance while caring for patients in every care setting. Although many of these disturbances are interrelated and may occur together, they are described here separately for learning purposes.

Fluid Imbalances

Fluid imbalances occur when the body's compensatory mechanisms are unable to maintain a homeostatic state. Fluid imbalances involve either the volume or distribution of water or electrolytes. Nursing implications related to fluid volume disturbances—including risk factors, nursing assessments, and interventions—are discussed later in the chapter.

Fluid Volume Deficit

FVD occurs when loss of ECF volume exceeds the intake of fluid (Hinkle et al., 2022). FVD involves a loss of both water and solutes in the same proportion from the ECF space. This state is known as **hypovolemia** or isotonic fluid loss. Both osmotic and hydrostatic pressure changes force the interstitial fluid into the intravascular space in an effort to compensate for the loss of volume in the blood vessels. As the interstitial space is depleted, its fluid becomes hypertonic, and cellular fluid is then drawn into the interstitial space, leaving cells without adequate fluid to function properly. FVDs result from the loss of body fluids, especially if fluid intake is decreased simultaneously.

Young children, older adults, and people who are ill are especially at risk for hypovolemia. FVD can rapidly result in a weight loss of 5% in adults and 10% in infants. A 5% to 10% decrease in weight can indicate mild to moderate fluid loss (Willis, 2020). A 15% weight loss caused by fluid deficiency usually is life threatening.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Recall **Jeremiah Stein**, the college student with an increased number of loose, watery stools for a week. Your assessment reveals that they have been limiting their oral intake, further compounding their risk for deficient fluid volume. Weighing Jeremiah would be an important intervention to include as part of the nursing assessment to help determine the extent of fluid loss.

Third-space fluid shift refers to a distributional shift of body fluids into the transcellular compartment, such as the pleural, peritoneal (ascites), or pericardial areas; joint cavities; the bowel; or an excess accumulation of fluid in the interstitial space. The fluid moves out of the intravascular spaces (plasma) to any of these spaces. Once trapped in these spaces, the fluid is not easily exchanged with ECF. With third-space fluid shift, a deficit in ECF volume occurs. The fluid has not been lost but is trapped in another body space for a period of time and is essentially unavailable for use. These fluid shifts may be related to a disruption in the colloid osmotic pressure (decreased albumin), increased fluid volume (excess IV fluid replacement, renal dysfunction), increased capillary hydrostatic pressure (heart failure), hyponatremia, or an increase in the permeability of the capillary membrane (gross tissue trauma). A third-space shift may occur as a result of burns, an acute intestinal obstruction, heart or liver failure, crush injuries, surgical procedures, or acute peritonitis (Willis, 2020). Decreased body weight does not occur as it does with an ECF volume deficit (vomiting or diarrhea), and the fluid loss cannot be measured.

Fluid Volume Excess

Excessive retention of water and sodium in ECF in near-equal proportions results in a condition termed *fluid volume excess (FVE).* FVE may be a result of fluid overload (excess water and sodium intake) or due to impairment of the mechanisms that maintain homeostasis (Bauldoff et al., 2020). Common causes include malfunction of the kidneys, causing an inability to excrete the excesses, and failure of the heart to function as a pump, resulting in accumulation of fluid in the lungs and dependent parts of the body.

Due to the increased extracellular osmotic pressure from the retained sodium and water, fluid is pulled from the cells to equalize the tonicity. By the time the intracellular and extracellular spaces are isotonic to each other, an excess of both water and sodium is in the ECF, whereas the cells are nearly depleted. The excessive ECF may accumulate in either the intravascular compartments (**hypervolemia**) or interstitial spaces (**edema**). Edema can be observed around the eyes, fingers, ankles, and sacral space, and can also accumulate in or around body organs. Accumulation of fluid may result in a weight gain in excess of 5%. The amount or severity of edema is typically graded (Fig. 41-9 on page 1680). Interstitial-to-plasma shift is the movement of fluid from the space surrounding the cells to the blood. Although the body attempts to maintain normal balance in all fluid spaces, the intravascular fluid is usually protected at the expense of interstitial fluid and ICF.

Remember **Jack Soo Park**, the patient who inadvertently received too much IV fluid? In Mr. Park's case, fluid accumulation involved his lungs and heart, exhibited by his bounding pulse, distended neck veins, and abnormal lung sounds.

Electrolyte Imbalances

Electrolyte imbalances commonly involve a deficit or excess of the electrolyte. Abnormalities in electrolyte levels can indicate fluid or acid–base imbalance, or neuromuscular, cardiac, renal endocrine, or skeletal dysfunction. Results from venous blood will provide essential information related to possible electrolyte imbalances. When patients present with deficits or excesses of sodium, potassium, calcium, magnesium, phosphate, or chloride, careful nursing assessment

depends on an understanding of the effects of these imbalances.

FIGURE 41-9. System for grading edema.

Hyponatremia and Hypernatremia

Sodium is the most abundant electrolyte in the ECF. Refer to Table 41-1 on page 1673. **Hyponatremia** refers to a sodium deficit in ECF (serum sodium <135 mEq/L) caused by a loss of sodium or a gain of water. Sodium may be lost through vomiting, diarrhea, fistulas, sweating, or as the result of the use of diuretics. The decrease in sodium causes fluid to move by osmosis from the less concentrated ECF compartment to the ICF space. This shift of fluid leads to swelling of the cells, with resulting confusion, hypotension, edema, muscle cramps and weakness, and dry skin. Severe hyponatremia (serum sodium <120 mEq/L) is manifested by signs of increasing intracranial pressure, which may include lethargy, muscle twitching, hyperreflexia, coma, and seizures; death may occur (Bauldoff et al., 2020).

Hypernatremia refers to a surplus of sodium in ECF (serum sodium >145 mEq/L) caused by excess water loss or an overall excess of sodium. Fluid deprivation, lack of fluid consumption (such as in patients who cannot perceive, respond to, or communicate thirst), diarrhea, and excess insensible water loss (hyperventilation, burns) lead to excess sodium. Rapid or excessive administration of sodium-containing intravenous solutions can also lead to an excess of sodium (Kamel & Halperin, 2017; Norris, 2020). Fluids move from the cells because of the increased extracellular osmotic pressure, causing them to shrink and leaving them without sufficient fluid. The cells of the central nervous system are especially affected, resulting in signs of neurologic impairment, including restlessness, agitation, weakness, disorientation, delusions, hallucinations, and seizures. Permanent brain damage, especially in infants and children, can occur.

Hypokalemia and Hyperkalemia

Potassium is the major intracellular electrolyte. Refer to Table 41-1 on page 1673. **Hypokalemia** refers to a potassium deficit in ECF (serum potassium <3.5 mEq/L) and is a common electrolyte abnormality. Potassium may be lost through vomiting, gastric suction, alkalosis, or diarrhea, or as the result of the use of diuretics. When the extracellular potassium level falls, potassium moves from the cell, creating an intracellular potassium deficiency. Sodium and hydrogen ions are then retained by the cells to maintain isotonic fluids. These electrolyte shifts influence normal cellular functioning, the pH of ECF, and the functions of most body systems, including the cardiovascular system. Skeletal muscles are generally the first to demonstrate a potassium deficiency. Typical signs of hypokalemia include muscle weakness and leg cramps, fatigue, paresthesias, and dysrhythmias (Willis, 2020).

Hyperkalemia refers to an excess of potassium in ECF (serum potassium >5 mEq/L). Excess potassium may result from renal failure, hypoaldosteronism, or the use of certain medications such as potassium chloride, heparin,

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

angiotensin-converting enzyme (ACE) inhibitors, nonsteroidal antiinflammatory drugs (NSAIDs), and potassium-sparing diuretics. Nerve conduction as well as muscle contractility can be affected. Skeletal muscle weakness, paraesthesias, and paralysis may occur. A variety of cardiac irregularities may result, including cardiac arrest if hyperkalemia is not corrected (Norris, 2020).

Hypocalcemia and Hypercalcemia

Calcium is a major component of bones and teeth. Refer to Table 41-1 on page 1673. **Hypocalcemia** refers to a calcium deficit in ECF (serum calcium <8.9 mg/dL, ionized calcium <4.5 mg/dL). Common causes related to a calcium deficit involve inadequate calcium intake, impaired calcium absorption, and excessive calcium loss. Manifestations of hypocalcemia include numbness and tingling of fingers, mouth, or feet; tetany; muscle cramps; and seizures.

Hypercalcemia refers to an excess of calcium in ECF (serum calcium >10.5 mg/dL, ionized calcium >5.6 mg/dL). Two major causes of hypercalcemia are cancer and hyperparathyroidism. Manifestations of hypercalcemia include nausea, vomiting, constipation, bone pain, excessive urination, thirst, confusion, lethargy, and slurred speech. Severe hypercalcemia (serum calcium ≥15 mg/dL) is an emergency situation (Sadiqu et al., 2020).

Hypomagnesemia and Hypermagnesemia

Magnesium is the most abundant intracellular cation after potassium. Refer to Table 41-1 on page 1673. **Hypomagnesemia** refers to a magnesium deficit in the ECF (serum magnesium <1.3 mEq/L). Magnesium loss may occur with nasogastric suction, diarrhea, chronic alcohol use, administration of tube feedings or parenteral nutrition, sepsis, or burns. This abnormality may lead to muscle weakness, tremors, tetany, seizures, cardiac arrhythmias, change in mental status, hyperactive deep tendon reflexes (DTRs), and respiratory paralysis.

Hypermagnesemia refers to a magnesium excess in the ECF (serum magnesium >2.1 mEq/L). It usually occurs with renal failure when the kidneys fail to excrete magnesium or from excessive magnesium intake (use of magnesium-containing antacids or laxatives) (Willis, 2020). Clinical manifestations include nausea, vomiting, weakness, flushing, lethargy, hypoactive DTRs, respiratory depression, coma, and cardiac arrest (Norris, 2020).

Hypophosphatemia and Hyperphosphatemia

Phosphorus is a critical element of all the body's tissues. Refer to Table 41-1 on page 1673. **Hypophosphatemia** refers to a below-normal concentration of phosphorus in the ECF (serum phosphate <2.5 mg/dL or 1.8 mEq/L). Although this may indicate phosphorus deficiency, multiple factors may lower serum phosphate levels while total body phosphorus stores are normal. Hypophosphatemia can result from administration of calories to malnourished patients, alcohol withdrawal, diabetic ketoacidosis, hyperventilation, absorption problems, and diuretic use. Manifestations include muscle weakness, slurred speech, dysphagia, decreased respiratory effort, paresthesias, irritability, confusion, seizures, and coma (Willis, 2020).

Hyperphosphatemia refers to above-normal concentrations of phosphorus in the ECF (serum phosphate >4.5 mg/dL or 2.6 mEq/L). Common causes are impaired kidney excretion and hypoparathyroidism. Hyperphosphatemia can result in hyperreflexia, anorexia, muscle weakness, decreased mental status, and dysrhythmias (Willis, 2020).

Hypochloremia and Hyperchloremia

Chloride is the major anion of the ECF. Refer to Table 41-1 on page 1673. **Hypochloremia** refers to below-normal level of chloride in the ECF (serum chloride <98 mEq/L). A low level of chloride can result from severe vomiting and diarrhea, drainage of gastric fluid (GI tube), metabolic alkalosis, diuretic therapy, and burns. Manifestations include hyperexcitability of muscles, tetany, hyperactive DTRs, weakness, and muscle cramps; severe hypochloremia may result in seizures, coma or respiratory arrest (Willis, 2020).

Hyperchloremia refers to an above-normal level of chloride in the ECF (serum chloride >108 mEq/L). Hyperchloremia can result from metabolic acidosis, hypernatremia, increased chloride retention by the kidneys, and hyperparathyroidism. Signs and symptoms include tachypnea, weakness, lethargy, diminished cognitive ability, decreased cardiac output, dysrhythmias, and coma.

Acid–Base Imbalances

Acid–base imbalances occur when the carbonic acid or bicarbonate levels become disproportionate. When there is a single primary cause, these disturbances are known as respiratory acidosis or alkalosis and metabolic acidosis or alkalosis, which are described in the sections that follow. Some references use the term *nonrespiratory* to refer to metabolic disturbances. Although these disturbances are discussed separately, combined disturbances frequently occur. Complicated clinical situations may occur when respiratory and metabolic imbalances coexist.

Metabolic Acidosis and Alkalosis

Metabolic acidosis and alkalosis occur as the result of metabolic processes. A metabolic or nonrespiratory disturbance alters the bicarbonate level in the ECF. It is reflected in the HCO_3^- level of an arterial blood gas (ABG). Both the lungs and the kidneys attempt to compensate for this disorder by either excreting or retaining $PaCO_2$ (the lungs) and/or HCO_3^- and H^+ ions (the kidneys).

Metabolic acidosis or *nonrespiratory acidosis* is a proportionate deficit of bicarbonate in ECF. The deficit can occur as the result of an increase in acid components or an excessive loss of bicarbonate. It can be produced by a gain of hydrogen ion or loss of bicarbonate. The lungs attempt to increase carbon dioxide excretion by increasing the rate and depth of respirations, which occurs within a short time. However, respiratory compensation is generally not adequate, and the kidneys attempt to compensate by retaining bicarbonate and by excreting more hydrogen. In summary: Metabolic acidosis = low pH (increased hydrogen ion concentration) and a low plasma bicarbonate concentration due to a gain of hydrogen or loss of bicarbonate.

Metabolic alkalosis or *nonrespiratory alkalosis* is associated with an excess of HCO_3, a decrease in H^+ ions, or both, in the ECF. This may be the result of excessive acid losses or increased base ingestion or retention. The body attempts to compensate by retaining carbon dioxide. The respirations become slow and shallow, and periods of no breathing may occur. The kidneys attempt to excrete excess H_2O and Na ions with the excessive bicarbonate and retain H^+ ions. In summary: Metabolic alkalosis = high pH and a high plasma bicarbonate concentration due to a gain of bicarbonate or a loss of hydrogen.

Respiratory Acidosis and Alkalosis

Respiratory acidosis and alkalosis occur as a result of respiratory disturbances. A respiratory disturbance alters the carbonic acid level in the ECF. It is reflected in the $PaCO_2$ level of an ABG. Compensation for a respiratory disturbance occurs when the lungs attempt to either retain or eliminate $PaCO_2$ from the body or when the kidneys attempt to restore balance through the conservation, formation, or excretion of bicarbonate (HCO_3^-).

Respiratory acidosis is a primary excess of carbonic acid in the ECF. It is produced by inadequate excretion of CO_2 with inadequate ventilation, resulting in elevated plasma CO_2 and increased levels of carbonic acid. Any decrease in alveolar ventilation that results in retention of carbon dioxide can cause respiratory acidosis. Initially, the increased amounts of CO_2 stimulate the medulla in the respiratory center to increase the respiratory rate. Due to the increase in respiratory rate, CO_2 is expelled, and the CO_2 level of the blood is reduced. If the respiratory response is not effective, the increasing CO_2 levels will stimulate the kidneys to eliminate H^+ ions (acids) and conserve bicarbonate and sodium ions. The $NaHCO_3$ acts to buffer the free acids and ultimately reduce the CO_2 levels and restore acid–base balance. In summary: Respiratory acidosis = high $PaCO_2$ due to alveolar hypoventilation.

Respiratory alkalosis is a primary deficit of carbonic acid in the ECF. It is the result of alveolar hyperventilation, breathing that is faster and deeper, and the consequent increase in the elimination of CO_2. This loss of CO_2 leads to a decrease in the carbonic acid level in the plasma and an increase in the pH. The chemoreceptors in the medulla sense the increase in pH and the presence of less carbonic acid and stimulate the body to breathe either more slowly or less deeply. If this condition lasts for about 6 hours or longer, the kidneys attempt to alleviate the imbalance by increasing the bicarbonate excretion and by retaining more hydrogen to correct the imbalance. In summary: Respiratory alkalosis = low $PaCO_2$ due to alveolar hyperventilation.

NURSING PROCESS FOR FLUID, ELECTROLYTE, AND ACID–BASE BALANCE

Assessing

Acute and chronic illness, trauma, and certain therapeutic interventions may place a patient at high risk for fluid, electrolyte, and acid–base imbalances. Such imbalances can seriously compromise the patient's health status and may prove life threatening. The nursing assessment can provide information to identify patients at high risk for fluid, electrolyte, and acid–base imbalances and patients with specific imbalances.

Nursing assessment related to fluid, electrolyte, and acid–base balance should include a nursing history, physical assessment, fluid intake and output, daily weights, and laboratory studies. When an imbalance in fluid, specific electrolytes, or acid–base balance is suspected, the nurse needs to incorporate the associated assessments into the patient's care. Physical assessment and clinical assessment parameters, nursing considerations, normal findings in a healthy adult, and possible abnormal or significant findings are outlined in Table 41-3 on pages 1683–1684 and Table 41-4 on page 1685.

Nursing History

A comprehensive nursing history includes questions related to the patient's fluid and electrolyte status and acid–base balance. The accompanying Focused Assessment Guide 41-1 (on page 1686) includes interview questions to help identify the patient's usual pattern of fluid intake and elimination and the patient's self-evaluation of hydration status and awareness of particular problems.

Interview questions are also directed toward identifying patients with health conditions that increase the risk for imbalances. Risk factors include the following:

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Acute and chronic illnesses (e.g., diabetes, congestive heart failure, renal failure)
- Abnormal losses of body fluids (e.g., prolonged or severe vomiting or diarrhea, draining wounds, fistulas)
- Burns
- Trauma
- Surgery
- Therapies that may disrupt fluid and electrolyte balance, for example, medications such as diuretics and steroids, and treatments such as IV therapy and parenteral nutrition (PN)

Physical Assessment

Physical assessment related to fluid, electrolyte, and acid–base balance includes the assessment of multiple body systems. Include assessment of the skin and mucous membranes, vital signs, and a neurologic assessment, as well as identification of relative symptoms or conditions such as excessive thirst, nausea, vomiting, diarrhea, draining wounds, or other fluid losses. Refer to Tables 41-3 (on page 1683–1684) and 41-4 (on page 1685). Assessment of other body systems should be included based on the patient's underlying health conditions.

Fluid Intake and Output

If monitoring of a patient's intake and output is required, alert the patient, family, and all caregivers to the need to measure all fluids entering and leaving the body. Refer to Guidelines for Nursing Care 41-1 (on page 1686) for an explanation of correct measurement of a patient's intake and output.

Daily Weights

The record of a patient's daily weight is an important gauge of fluid balance (Bauldoff et al., 2020). Acute weight loss or gain represents fluid gain or loss (1 liter [L] of water weights 1 kg [2.2 lb]) (Norris, 2020). Weigh the patient at the same time every day. Be alert for other factors that may affect a patient's weight, such as using a different scale and weighing with the patient wearing significantly different clothing.

Table 41-3 Parameters to Be Considered in Physical Assessment for Fluid, Electrolyte, and Acid–Base Balance

ASSESSMENT PARAMETERS	NURSING CONSIDERATIONS	FINDINGS IN HEALTHY ADULT	SIGNIFICANT FINDINGS
Skin turgor (elasticity)	• The patient's skin over the sternum, inner aspect of the thighs, or forehead is pinched. • Some prefer to test skin turgor in children over the abdominal area and on the medial aspect of the thighs. • Skin turgor can vary with age, nutritional state, ethnicity, and complexion.	• Pinched skin immediately falls back to its normal position when released. • Reduced skin turgor is common in older adults because of a primary decrease in skin elasticity.	• In fluid volume deficit, the skin flattens more slowly after the pinch is released; the skin may remain elevated for many seconds. • Severe malnutrition, particularly in infants, can cause depressed skin turgor even in the absence of fluid depletion.
Tongue turgor	• Tongue turgor is not affected appreciably by age and thus is a useful assessment for all age groups. (In an arid climate, this may not be a reliable parameter.)	• Tongue has one longitudinal furrow.	• In fluid volume deficit, there are additional longitudinal furrows, and the tongue is smaller. • Sodium excess causes the tongue to look red and swollen.
Moisture and oral cavity	• A dry mouth may be the result of fluid volume deficit, mouth breathing, or exposure to an arid climate.	• Mucous membranes in oral cavity are moist.	• Dryness of the membrane where the cheek and gum meet indicates fluid volume deficit. • Dry sticky mucous membranes are noted in sodium excess.

Tearing and salivation		• Tearing and salivation decrease normally with age.	• The absence of tearing and salivation in a child is a sign of fluid volume deficit.
Appearance of skin and skin temperature			• Metabolic acidosis can cause warm, flushed skin (due to peripheral vasodilation).
Facial appearance			• A person with a severe fluid volume deficit may have a pinched and drawn facial expression. • A fluid volume deficit of 10% of body weight causes decreased intraocular pressure, causing the eyes to appear sunken and to feel soft to the touch.
Edema (excessive accumulation of interstitial fluid)	• Pitting edema (see Fig. 41-9) • Measurement of an extremity or body part with a millimeter tape, in the same area each day, is a more exact method of measurement. • An excess of interstitial fluid may accumulate predominantly in the lower extremities of ambulatory patients and in the presacral region of bedridden patients.	• No edema	• Clinically, edema is not usually apparent in the adult until the retention of 5–10 lb of excess fluid occurs. • Formation of edema may be localized (as in thrombophlebitis) or generalized (as in heart failure, cirrhosis of the liver, or nephrotic syndrome).
Body temperature	• Fever increases the loss of body fluids. • Body temperature and other vital signs should be assessed as prescribed, indicated in facility policies and procedures, and at the nurse's discretion.	• Baseline temperature	• A temperature elevation between 101°F (38.3°C) and 103°F (39.4°C) increases the 24-hour fluid requirement by at least 500 mL, and a temperature above 103°F increases it by at least 1,000 mL.
Pulse		• Baseline pulse rate, rhythm, and quality.	• Tachycardia is usually the earliest sign of the decreased vascular volume associated with fluid volume deficit. • Irregular pulse rates also occur with potassium imbalances and magnesium deficit. • Pulse quality/amplitude is decreased in fluid volume deficit and increased in fluid volume excess.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Respirations		• Baseline respiratory rate, rhythm, and depth	• Deep, rapid respirations may be a compensatory mechanism for metabolic acidosis or a primary disorder causing respiratory alkalosis. • Slow, shallow respirations may be a compensatory mechanism for metabolic alkalosis or a primary disorder causing respiratory acidosis. • Moist crackles may indicate fluid volume excess.
Blood pressure	• Whenever a fluid imbalance is suspected, the patient's blood pressure is measured in the supine, sitting, and standing position to determine the presence of orthostatic changes	• Baseline blood pressure	• A sustained decrease in systolic blood pressure of ≥20 mm Hg or a decrease in diastolic blood pressure of ≥10 mm Hg (postural hypotension) may indicate fluid volume deficit.

Source: Adapted from Hale, A., & Hovey, M. J. (2014). Fluid, electrolyte, and acid-base imbalances. F.A. Davis; Hinkle, J. L., Cheever, K. H., & Overbaugh, K. J. (2022). Brunner & Suddarth's Textbook of medical-surgical nursing (15th ed.). Wolters Kluwer; and Norris, T. L. (2020). Porth's essentials of pathophysiology (5th ed.). Wolters Kluwer.

Laboratory Studies

Laboratory tests are helpful in determining whether fluid, electrolyte, and acid–base balance exist. Descriptions of standard tests follow; tables of normal values are available in Appendix C.

COMPLETE BLOOD COUNT

The complete blood count determines the total number of red blood cells and values for hemoglobin and hematocrit. Significant values include the following:

- Increased hematocrit values: found in severe fluid volume deficit and shock (when hemoconcentration rises considerably)
- Decreased hematocrit values: found with acute, massive blood loss, and with hemolytic reaction after transfusion of incompatible blood or with fluid overload
- Increased levels of hemoglobin: found in hemoconcentration of the blood
- Decreased levels of hemoglobin: found with anemia states, severe hemorrhage, and after a hemolytic reaction

SERUM ELECTROLYTES, BLOOD UREA NITROGEN, AND CREATININE LEVELS

This screening test determines plasma levels of certain electrolytes such as sodium, potassium, chloride, and bicarbonate ions. In addition, the blood urea nitrogen (BUN) and creatinine levels can provide information related to the fluid status and the renal function of the patient. Significant values include the following:

- Below-normal or above-normal levels of sodium, potassium, calcium, magnesium, phosphate, and chloride. Refer to the electrolyte imbalance discussion earlier in the chapter.
- Below-normal or above-normal levels of bicarbonate ions. Refer to the acid–base discussion earlier in the chapter and the ABGs discussion later in this section.
- Increased BUN: found with impaired renal function (such as associated with shock, heart failure, and salt and water depletion), diabetic ketoacidosis, burns
- Increased creatinine: found with impaired renal function, heart failure, shock, fluid volume deficit

Table 41-4 Parameters to Be Considered in Clinical Assessment for Fluid,

	Electrolyte, and Acid–Base Balance		
ASSESSMENT PARAMETERS	**NURSING CONSIDERATIONS**	**FINDINGS IN HEALTHY ADULT**	**SIGNIFICANT FINDINGS**
Comparison of total intake and output of fluids	• Records may be initiated for any patient with a real or potential fluid or electrolyte problem. • Intake should include all fluids taken into the body. • Output should include urine, vomitus, diarrhea, drainage from fistulas, and drainage from suction apparatus. Perspiration and drainage from lesions should be noted	• Fluid intake approximately equals fluid output—when averaged over 2 or 3 days. • Average adult intake and loss per day is 2,600 mL.	• When the total intake is substantially less than the total output, the patient is in danger of fluid volume deficit. • When the total intake is substantially more than the total output, the patient is in danger of fluid volume excess.
Urine volume and concentration	• All fluid losses are measured according to routes. • A device calibrated for small volumes of urine is used when hourly urine volumes need to be measured. • Factors that can alter urinary output must be accounted for, including amount of fluid intake; losses from skin, lungs, and GI tract; renal concentrating ability; blood volume; and influence of aldosterone and ADH	• Normal urinary output for the average adult: 1,500 mL/24 hr.; about 40–80 mL/hr. • The range of specific gravity is from 1.005 to 1.030. Urine osmolality ranges between 500 and 800 mOsm/kg (mmol/kg).	• A low urine volume and high specific gravity indicates fluid volume deficit. • A low urine volume and low specific gravity indicates renal disease. • A high urine volume suggests fluid volume excess. • Hypovolemia causes decreased renal perfusion and oliguria; hypervolemia causes increased urinary volume if the kidneys are functioning normally.
Body weight	• Because of the common inaccuracies in recording intake and output, body weight is believed to be a more accurate indicator of fluid gained and lost. • A patient may have a severe fluid volume deficit even though body weight is essentially unchanged when there is a third-space loss of body fluid.	• A patient's dry weight should remain relatively stable.	• Rapid variations in weight closely reflect changes in body fluid volume. • A rapid gain or loss of 1 kg (2.2 lb) of body weight is about equal to the gain or loss of 1 L of fluid.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Recall **Grace Gilligan**, the female described in one of the beginning scenarios. Although she needs IV therapy, it would be important for the nurse to determine the patient's electrolyte levels to establish a baseline to aid in determining the best IV solution for the patient and to determine the need for electrolyte replacement.

URINE pH AND SPECIFIC GRAVITY

Both the urine pH and specific gravity may be obtained by dipstick measurement, using a fresh voided specimen or through laboratory analysis. The pH of urine usually ranges between 4.6 and 8.2. Lower-than-normal urinary pH can occur with metabolic acidosis, diabetic ketosis, and diarrhea. Higher-than-normal urinary pH can occur with respiratory alkalosis, potassium depletion, and chronic renal failure. Specific gravity is a measure of the urine's concentration. The range depends on the patient's state of hydration and varies with urine volume and the load of solutes to be excreted. Normal values range from 1.005 to 1.030 (concentrated urine, ≥1.025; dilute urine, ≤1.001 to 1.010). Increased urine specific gravity can occur with dehydration, vomiting, diarrhea, and heart failure. Decreased urine specific gravity can occur with renal damage.

ARTERIAL BLOOD GASES

Arterial blood gases (ABGs) are laboratory tests commonly used to determine the adequacy of oxygenation and ventilation as well as in the assessment and treatment of acid–base imbalance. The ABG findings are obtained through analysis of an arterial blood sample. The pH of the plasma or blood indicates balance or impending acidosis or alkalosis. The blood's oxygen and carbon dioxide gas values are also reported, providing information regarding the effectiveness of the respiratory system. The partial pressures (indicated by "P") of these gases, or their tensions, are determined by the use of a nomogram, which reflects the chemical and physical activities of the two gases. The partial pressure of carbon dioxide is abbreviated $PaCO_2$; for oxygen, it is PaO_2. The "a" indicates an arterial specimen. When the PaO_2 is low, hemoglobin carries less-than-normal amounts of oxygen; when the PaO_2 is high, the hemoglobin carries more oxygen. The $PaCO_2$ is influenced almost entirely by respiratory activity. When the $PaCO_2$ is low, carbonic acid leaves the body in excessive amounts; when the $PaCO_2$ is high, there are excessive amounts of carbonic acid in the body. Oxygen saturation readings (SaO_2) reveal the percentage of oxygen in the blood that combines with hemoglobin.

Focused Assessment Guide 41-1

FLUID, ELECTROLYTE, AND ACID–BASE BALANCE

Factors to Assess	Questions and Approaches
Usual patterns of fluid intake	Describe the amount and types of fluids you usually drink in a 24-hour period. Have there been any recent changes?
Usual pattern of fluid elimination	Describe your usual voiding/urination habits. Any recent changes in frequency or amount? Is your body losing fluids in any other major way? • Vomiting • Diarrhea • Excessive perspiration • Fistula
Patient's evaluation of hydration status	Do you think there is an approximate balance between your fluid intake and output? Have you noticed any signs that your body is experiencing too much or too little hydration (difficulty breathing, edema, dry skin and mucous membranes, thirst)?
History of disease process	Is there any history of disease process or injury that might disrupt fluid and electrolyte balance (e.g., diabetes mellitus, cancer, burns)?
Medication/nutrition history	Do you take any medications or treatments that might disrupt fluid and electrolyte balance (e.g., steroids, diuretics, parenteral nutrition, dialysis)? Have you been trying to lose weight by dieting, using diuretics, laxatives, or diet aids? Have you been following a high-protein, low-carbohydrate diet?
Fluid, electrolyte, and acid–base imbalances and contributing factors	Are you aware of any other fluid balance problems you may be experiencing? • Nature

- Onset of problem and frequency
- Causes
- Severity
- Symptoms
- Intervention attempted and results

Guidelines for Nursing Care 41-1

Measuring Fluid Intake and Output

- Instruct the patient and family/caregiver regarding the need for a record of all fluids entering the body and all fluid output. Provide an explanation of the rationale along with instructions for how the patient can help keep measurements accurate. Some patients may need to be reminded each morning that this measurement will continue.
- Use the patient's plan of care to communicate to other nursing personnel the need to measure fluid intake and output.
- A sign posted in the patient's room and a bedside form for recording intake and output are helpful reminders for both the patient and nurses.
- Measure both intake and output whenever possible, rather than estimate.
- Record intake and output totals for each 8-hour shift and total each 24 hours. If the nurse suspects a large difference between intake and output, total the columns earlier so that the health care team can be notified.

Patient's Fluid Intake Includes the Following

- All fluids and foods that are liquid at room temperature (ice cream, gelatin dessert [Jell-O], and the like)
- Use the facility's designation of specific volumes for common food containers (e.g., juice glass, 90 mL; milk carton, 240 mL). Remind the patient that sips of water or other fluids in between meals need to be recorded. Remember that liquid medications or water taken with pills may significantly increase the fluid intake of some patients.
- All parenteral fluids
- Other fluids taken into the body: subcutaneous fluids, gastrointestinal tube feedings and flushes; IV flushes

Patient's Fluid Output Includes the Following

- Urine; vomitus; diarrhea; drainage from fistulas, wounds, and ulcers; and drainage from suctioning devices or other tubes. Calibrated measuring devices should be readily available for accurate measurement. Disposable, calibrated urine collection containers that fit under the toilet seat are available for ambulatory patients. Urine or liquid feces in diapers or bed clothes, vomitus on clothing or bed linens, wound drainage saturating dressings, and so forth, need to be estimated.
- Heavy perspiration, noted on the output record, especially when the patient's clothing or bed linens are soaked.
- Hyperventilation (water vapor loss) also noted on the output record. Record the rate and depth of respirations.

Table 41-5 Acid–Base Parameters for Arterial Blood Gas Studies

	NORMAL	ACID	BASE
pH	7.35–7.45	<7.35	>7.45
$PaCO_2$ (mm Hg)	35–45	>45	<35
HCO_3^- (mEq/L)	22–26	<22	>26

The bicarbonate level (HCO_3^-) of the ABG report reflects the bicarbonate level of the body. The kidneys are involved in either reabsorbing bicarbonate or excreting bicarbonate, depending on what is needed to maintain the delicate acid–base balance.

Although compensation is the body's natural attempt to restore balance, correction may also be required. Correction involves using medical and nursing interventions to promote a return to homeostasis (e.g., pharmacologic agents, mechanical ventilation, monitor intake/output, dietary teaching). Table 41-5 outlines acid–base parameters for ABG studies.

Additional ABG values exist but are not included in this simple interpretation of acid–base imbalances. Partial pressure of oxygen (PaO_2) and oxygen saturation (SaO_2) results also directly reflect the adequacy of oxygenation and ventilation. Follow these steps when interpreting ABGs:

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

1. **Determine whether the pH is alkalotic or acidotic.**
   Remember, the optimal pH is 7.4, but body will tolerate a pH from 7.35 to 7.45. If the pH is lower than 7.35, the patient is acidotic. If the pH is higher than 7.45, the patient is alkalotic. If the pH is within the normal range, determine which side of 7.4 it lies on (lower or higher). This may indicate the patient is acidotic or alkalotic, but the body is compensating to make the pH closer to normal (Woodruff, 2006).
2. **Look at the $PaCO_2$.**
   Remember, carbon dioxide is produced by cellular metabolism and is excreted by the lungs through exhalation. It represents the respiratory component of the blood gas. Normal levels range from 35 to 45 mm Hg. Changes in the $PaCO_2$ reflect lung function. A $PaCO_2$ level below 35 mm Hg can be caused by hyperventilation, resulting in alkalosis. When the patient retains CO_2, as a result of hypoventilation, for example, the $PaCO_2$ level rises above 45 mm Hg, resulting in acidosis.
3. **Look at the HCO_3^-.**
   Remember, bicarbonate is produced by the kidneys. It represents the metabolic component of the blood gas. Normal levels range from 22 to 26 mEq/L. Changes in the HCO_3^- reflect kidney function. A HCO_3^-level below 22 mEq/L indicates acidosis and above 26 mEq/L indicates alkalosis.
4. **Look at the $PaCO_2$ or the HCO_3^- and match either with the pH.**
   If the pH is low and the $PaCO_2$ is high, the patient has respiratory acidosis. If the pH is high and the $PaCO_2$ is low, the patient has respiratory alkalosis. If the pH and $HCO_3^-$are high but the $PaCO_2$ is normal, the patient has metabolic alkalosis. The patient has metabolic acidosis if the pH and $HCO_3^-$are low and the $PaCO_2$ is normal (Willis, 2020).
   Respiratory acidosis:
   ↓ pH <7.35 ↑ $PaCO_2$ Normal HCO_3^-
   Respiratory alkalosis:
   ↑ pH >7.45 ↓ $PaCO_2$ Normal HCO_3^-
   In metabolic acid–base imbalances, the pH and HCO_3^- values are both high or both low:
   Metabolic acidosis:
   ↓ pH <7.35 ↓ HCO_3^- Normal $PaCO_2$
   Metabolic alkalosis:
   ↑ pH >7.45 ↑ HCO_3^- Normal $PaCO_2$
5. **Look at the total picture and determine whether compensation has occurred.**
   Determine whether the body is compensating for the pH change. Complete compensation occurs when the body's ability to compensate is so effective that the pH falls within the normal range (Willis, 2020). Partial compensation occurs when the pH remains outside the normal range (Willis, 2020). Compensation involves opposites: for example, in primary metabolic acidosis, compensation involves respiratory alkalosis; in primary respiratory acidosis, compensation involves metabolic alkalosis. Determine which level more closely corresponds with the pH, indicating the primary cause of the problem. The other level reflects the compensation.
   Example:
   pH↓ 7.29
   $PaCO_2$ ↓17 mm Hg
   HC ↓ 19 mEq/L
   The low pH indicates acidosis; the $PaCO_2$ is low, which normally leads to alkalosis, and the bicarbonate level is low, which normally leads to acidosis. In this example, the bicarbonate level more closely corresponds with the pH, making the primary cause of the problem metabolic. The resultant decrease in $PaCO_2$ reflects partial respiratory compensation—metabolic acidosis with partial respiratory compensation (Willis, 2020). When compensation occurs, the $PaCO_2$ and the HCO_3^- will always point in the same direction.
6. **Look at the PaO_2 and SaO_2.**
   The PaO_2 and SaO_2 provide information about the patient's oxygenation status. If the PaO_2 is less than 80, or the SaO_2 is less than 95%, the patient has hypoxemia.

Table 41-6 (on page 1688) identifies risk factors, assessments, and potential nursing interventions related to these acid–base disturbances.

Table 41-6 Acid–Base Disturbances

RISK FACTORS	ASSESSMENTS	NURSING INTERVENTIONS
Respiratory Acidosis		
Acute respiratory disease	Acute respiratory acidosis	Treatment is directed at improving

Pulmonary edema Aspiration of a foreign body Atelectasis Overdose of sedative or anesthetic Cardiac arrest Chronic respiratory disease Emphysema Bronchial asthma Cystic fibrosis Inadequate mechanical ventilation CNS depression Neuromuscular disease	Mental cloudiness Dizziness Muscular twitching Unconsciousness ABGs pH <7.35 $PaCO_2$ >45 mm Hg (primary) HCO_3^- normal or only slightly elevated Chronic respiratory acidosis Weakness Dull headache ABGs pH <7.35 or low N $PaCO_2$ >45 mm Hg (primary) HCO_3^- >26 mEq/L (compensatory)	ventilation Pharmacologic measures Pulmonary hygiene measures Adequate hydration Supplemental oxygen Mechanical ventilation may be necessary to correct disorder but must be used cautiously to decrease $PaCO_2$ slowly.
Respiratory Alkalosis		
Hyperventilation Extreme anxiety (most common cause) Hypoxemia High fever Early sepsis Excessive ventilation by mechanical ventilator CNS lesion involving the respiratory center	Lightheadedness Inability to concentrate Hyperventilation syndrome Tinnitus Palpitations Sweating Dry mouth Tremulousness Convulsions and loss of consciousness ABGs pH >7.45 $PaCO_2$ <35 mm Hg (primary) HCO_3^- <22 mEq/L (compensatory)	If anxiety is the cause, encourage the patient to breathe more slowly (causes accumulation of CO_2) or breathe into a closed system (paper bag). Sedative may also be necessary in extreme anxiety. Treatment of other causes is directed at correcting the underlying problem.
Metabolic Acidosis		
Diarrhea Intestinal fistulas Parenteral nutrition Excessive intake of acids, such as salicylates Diabetic ketoacidosis Renal failure Starvational ketoacidosis	Headache Confusion Drowsiness Increased respiratory rate and depth Nausea and vomiting Peripheral vasodilation ABGs pH <7.35 HCO_3^- <22 mEq/L (primary) $PaCO_2$ <35 mm Hg Hyperkalemia frequently present	Treatment is directed toward correcting the metabolic deficit. If the cause of the problem is excessive intake of chloride, treatment obviously focuses on eliminating the source. When necessary, bicarbonate is administered.
Metabolic Alkalosis		
Vomiting or gastric suction Hypokalemia Potassium-wasting diuretics Alkali ingestion (bicarbonate-containing antacids) Renal loss of H^+ (e.g., from steroid or diuretic use)	Dizziness Tingling of fingers and toes Hypertonic muscles Depressed respirations (compensatory) ABGs pH >7.45 HCO_3^- >26 mEq/L (primary) $PaCO_2$ >45 mm Hg (compensatory) Hypokalemia may be present	Treatment is aimed at reversal of the underlying disorder. Sufficient chloride must be supplied for the kidney to absorb sodium with chloride (allowing the excretion of excess bicarbonate). Treatment also includes administration of NaCl fluids to restore normal fluid volume.

Examples of Actual or Potential Health Problems and Needs

FLUID, ELECTROLYTE, AND ACID–BASE BALANCE

Actual or Potential Health Problems and Needs	Possible Etiologic Factors	Potential Signs and Symptoms
Fluid overload	Renal failure, decreased cardiac output, excessive IV infusion/fluid intake, excessive sodium intake	• "I've noticed that my wedding ring is tight … also my clothes don't fit as well as they used to. I guess I've gained some weight." • Reports dyspnea with exertion, feeling weak and fatigued • Pitting edema in feet, ankles, lower legs, taut, shiny skin • Adventitious breath sounds and increased blood pressure • 10-lb (4.5-kg) weight gain over past month
Fluid imbalance	Inability to obtain or swallow fluids (debilitation, oral pain), extremes of age, vomiting, diarrhea, burns, excessive use of laxative, excessive diaphoresis, fever	• Change in mental status • Increased body temperature and pulse rate, decreased blood pressure • Dry oral mucosa, cracked lips, furrowed tongue, decreased skin turgor • Scanty, dark urine output • Sudden weight loss: 5 lb (2 to 3 kg)
Impaired fluid intake	Inability to access fluids, extremes of age, insufficient knowledge about fluid needs	• "I only drink a little liquid with my meals. I don't want to have to go to the bathroom while I'm out with friends. And I never drink anything after dinner, so I don't have to get up at night!" • Voiding small amounts concentrated urine; urine specific gravity 1.035 • Fluid intake inconsistent and less than 1,500 mL/day • Skin dry, less supple

Diagnosing Actual or Potential Health Problems and Needs

An assessment of a patient's fluid, electrolyte, and acid–base status may lead to the identification of one or more actual or potential health problems and needs related to fluid, electrolyte, and acid–base balance. Following the formulation of the actual or potential health problems and needs, the nurse communicates findings to other nursing and health care professionals through the use of written and spoken word. The written actual or potential health problem or need becomes a permanent part of the patient's health record. Examples of health problems and needs with related etiology and signs and symptoms can be found in the Examples of Actual or Potential Health Problems and Needs: Fluid, Electrolyte, and Acid–Base Balance.

Outcome Identification and Planning

Expected outcomes are derived from the actual or potential fluid, electrolyte, and acid–base balance problems or needs identified. The goal is to maintain or restore optimum function related to fluid, electrolyte, and acid–base balance, alleviate symptoms or side effects of disease or treatment, and prevent complications. General patient outcomes are listed here. Actual patient outcomes should list specific behaviors and criteria individualized for the patient situation.

Nursing care supports the following expected outcomes. The healthy adult patient will:

- Maintain an approximate balance between fluid intake and fluid output (average about 2,500 mL fluid intake and output/day over 3 days)
- Maintain a urine specific gravity within normal range (1.005 to 1.030)
- Practice self-care behaviors to promote fluid, electrolyte, and acid–base balance; maintain adequate intake of fluid and electrolytes; and respond appropriately to the body's signals of impending fluid, electrolyte, or acid–base imbalance.

When an imbalance exists, the patient will:

- Report relief of symptoms (specify) after implementation of treatment regimen (e.g., 1 month after decreasing sodium intake patient reports weight loss of 4 lb [1.8 kg])
- Exhibit signs and symptoms of restored balance or homeostasis after initiation of treatment
- Identify signs and symptoms of recurrence of imbalance with need to notify the health care team.

Implementing

Nursing interventions to prevent or correct fluid, electrolyte, and acid–base imbalances include dietary modification, modification of fluid intake, medication administration, IV therapy, blood and blood products replacement, administration of PN, allaying anxiety as needed, and appropriate patient and family/caregiver teaching.

Preventing Fluid and Electrolyte Imbalances

An adequate fluid intake and a well-balanced, nutritious diet with appropriate adjustments throughout the life cycle are essential to promoting fluid balance. The following are general measures to consider that will help prevent fluid imbalances:

- Be familiar with common life events that can lead to fluid imbalances and observe the patient carefully. Infants are particularly vulnerable to fluid imbalances because body water accounts for a greater percentage of their weight, and fluid fluctuations are more common. Loss of fluid because of an illness can cause serious and life-threatening problems in infants.
- Note the patient's present fluid and food intake and obtain a history of the patient's previous eating and drinking patterns. Learn whether the patient has been using a fad diet, which may lead to imbalances.
- Note whether the patient experiences excessive thirst or little or no thirst. Thirst, a subjective sensation, is an important factor determining water intake and, eventually, output through the kidneys. Although the thirst mechanism is poorly understood, both psychological and physiologic factors appear to be involved. An older adult is more susceptible to fluid-deficient conditions related to a less effective thirst mechanism (Eliopoulos, 2018). Be aware of excessive losses of fluids from the body, and attempt to prevent losses when possible. Vomiting, pronounced perspiration, diarrhea, draining wounds, and excessive urinary output, for example, may cause excessive losses.
- Consider ways in which the patient's medical regimen may lead to fluid and electrolyte imbalances. For example, diuretics that stimulate urine formation may increase the elimination of both fluid and potassium. If food supplements high in potassium are not included in the diet or if potassium supplement drug therapy is not started, hypokalemia often follows.
- Learn whether the patient has been self-administering a treatment that may threaten fluid balance. Common practices that threaten fluid balance include the indiscriminate use of enemas, laxatives, antacids, and over-the-counter drugs or herbal medications to promote urination.
- Consider conditions with destructive effects on the body as threats to fluid balance. Examples include immobilization, trauma, burns, surgical procedures, and exposure to toxic agents.
- Teach patients to observe for signs and symptoms of fluid imbalances and to report them promptly. Examples include rapid weight gains and losses; swollen fingers, feet, and ankles; puffy eyelids; muscle weakness; change in skin sensations; and scanty or profuse urine production.
- Help patients and their families/caregivers understand the significance of maintaining fluid balance and preventing imbalances.
- Be aware that normal physiologic changes associated with aging affect older adults' ability to maintain fluid balance. Fluid volume deficit is a common fluid and electrolyte disorder in this population. The accompanying Focus on the Older Adult box suggests specific nursing strategies to prevent and correct fluid and electrolyte imbalances in older adults.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Focus on the Older Adult

NURSING STRATEGIES TO ADDRESS AGE-RELATED CHANGES AFFECTING FLUID BALANCE

Age-Related Changes	Nursing Strategies
• Decreased sense of thirst • Medical conditions (e.g., heart failure or hypertension, requiring medications such as diuretics)	• Ensure that oral intake is at least 1,500 mL for 24 hours. • Be aware of schedule for diagnostic tests (and associated dietary and fluid restrictions). • Offer fluids at regular intervals. • Replace fluids as necessary, either orally or intravenously. • Investigate individual fluid preferences. • Provide assistance or assistive devices for encouraging fluid intake.
Alterations in Renal Functioning	
• Loss of nephrons • Decreased renal blood flow	• Record accurate intake and output. • Note appearance and specific gravity of urine. • Check laboratory values for abnormal levels.
Alterations in Cardiac Functioning	
• Decreased efficiency as a pump • Volume intolerance	• Monitor breath sounds. • Assess for shortness of breath, wet productive cough, increased respiratory rate and work of breathing, edema. • Monitor chest radiograph.

Promoting Health Literacy

IN PATIENTS WITH FLUID OR ELECTROLYTE IMBALANCES

Patient Scenario

Shamala Johnson, 58, had been experiencing complications from diabetes for the previous 10 years. She tells the nurse, “I really thought that I had things under control until lately. I can’t believe one more thing has happened.” Ms. Johnson was admitted to the hospital with end-stage renal failure. “I guess I knew this was coming eventually but did not expect it so soon!” She initially received dialysis via a temporary dialysis catheter but had surgery yesterday for placement of an A-V shunt. Her current plan of care includes dietary modifications, including potassium, sodium, protein, and fluid restrictions. The nurse has assisted her with making dietary choices based on the hospital menus and has arranged a consult with the dietitian. The patient asks, “Do you think I will have to keep this up at home? How will I manage to get the right food? And liquids, can I drink anything? I don’t understand this at all!”

Nursing Considerations: *Tips for Improving Health Literacy*

Confirm her dietary modifications for after discharge. Provide Ms. Johnson with easy-to-read information about living with renal disease, and managing fluid and electrolytes, as well as protein restrictions. Encourage her to ask her health team members as many questions as needed to understand her condition. Explain that there are things she can do to feel in control and follow the suggested regimen. Provide information and resources for support at home. Encourage Ms. Johnson to ask her primary care provider the following three questions:

- What is my main problem?
- What do I need to do?
- Why is it important for me to do this?

What additional measures can you take to help increase health literacy in this patient? What other measures would be helpful for this patient if she did not speak English, could not read, or had other learning deficits?

Information related to risk factors, related assessments, and specific nursing interventions for fluid volume disturbances and electrolyte disturbances can be found in the Supplemental Resources for this text online.

Developing a Dietary Plan

Teach patients about their health conditions and provide information and support to improve health literacy in patients. Refer to the accompanying Promoting Health Literacy box. Simple dietary changes may help to resolve fluid and electrolyte disturbances. After obtaining a nutritional assessment to identify actual or potential imbalances and food preferences (refer to Chapter 37), initiate teaching based on a nutritional plan that involves both the patient and the person who prepares the patient's meals. Include foods that help to resolve the fluid or electrolyte imbalance and that are acceptable to the patient. For example, for fluid volume deficit, increase foods with high water content (e.g., citrus fruit, melons, celery); for hypokalemia, increase foods with high potassium content (e.g., bananas, citrus fruits, apricots, melons, broccoli, potatoes, raisins, lima beans); and for hypernatremia, avoid foods high in sodium (e.g., processed cheese, lunch meats, canned soups and vegetables, salted snack foods) and eliminate the use of table salt.

When teaching the patient about foods to include or avoid, provide the patient with a written list for reference. Evaluate the patient's understanding of the teaching by having the patient identify foods that can be eaten freely or moderately as well as those to be avoided. Both the patient and person responsible for the patient's food preparation should be able to describe a 24-hour nutrition plan compatible with the recommended modifications.

Modifying Fluid Intake

Depending on the nature of the fluid or electrolyte imbalance, a patient's fluid intake may need to be increased, decreased, or modified in terms of types of fluids ingested. Nursing responsibilities include:

- Identifying the appropriate fluid modification (e.g., with certain illnesses, there may be a prescribed intervention to "Restrict fluids to 1,000 mL daily")
- Determining whether the patient understands the rationale for the fluid modification, is motivated to follow the modification, and is capable of adhering to the plan (e.g., a bedridden patient who needs to increase fluid intake cannot do this independently)
- Developing and implementing a plan of care based on the preceding information

INCREASING FLUIDS

Increasing fluids involves actions to achieve an above-average intake of fluids. A prescribed intervention to encourage or increase fluids indicates the amount of fluid the patient is to have in each 24-hour period. Typically, the plan of care specifies the amount of fluid to be ingested in 24 hours (for hospitalized patients, shift totals are helpful [e.g., 7 to 3, 1,200 mL; 3 to 11, 900 mL; 11 to 7, 300 mL]) and the patient's food preferences. Choose or assist with choosing fluids that best provide the calories and electrolytes needed by the patient.

Several interventions can be implemented to help the patient consume more than average amounts of fluids. Begin by explaining to the patient in understandable terms the rationale for the increased fluids and the specific goal of taking the daily amount of fluid prescribed. This explanation provides the patient with a greater understanding of the reason for the increase in fluid intake. In addition, this information helps motivate the patient to engage in the planned interventions. Together with the patient, develop short-term goals for accomplishing the increased fluid intake. For example, the patient will drink a glass of water every hour, a particular beverage by the time a television program is finished, or a pitcher of water by lunch. In general, patients are more likely to reach set goals when they have been involved in setting these goals.

Ensure that a proportionately larger amount of fluid is offered during the early hours of the patient's waking day, rather than large amounts before bedtime. The patient can usually take fluids relatively easily after having few or no fluids during sleeping hours. However, large amounts of fluid at night interferes with the patient's ability to rest and sleep by being awakened during the night with the need to urinate.

Offering a variety of fluids served at the appropriate temperature is helpful, as is allowing the patient to indicate a preference. The likelihood for success also is increased because the patient is more likely to drink more when some liquids are iced and cold and when coffee or tea is hot. Variety also adds interest and makes increasing fluids more palatable. If patients dislike taking fluids (a common problem with children) or have swallowing difficulties, offering a gelatin dessert, flavored frozen water (popsicles), water ice, or other alternative sources of liquid may meet with more success.

Always have fluids readily available for the patient. Take care to avoid a situation in which patients are unable to secure their own fluids (left with an unfilled water pitcher, an empty glass, a full pitcher out of reach, or a pitcher too heavy to lift). In addition, use attractive, clean, and easy-to-handle cups, glasses, and straws and practices that help to encourage the patient's desire to take fluids.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Recall **Jeremiah Stein**, the student with frequent loose stools. The nurse should discuss the need for increased fluid intake to compensate for fluid lost with the loose stools with Jeremiah. Students are often on tight budgets; it would be important to determine if he has access to or is able to obtain appropriate fluids.

Patient/family/caregiver participation in care promotes autonomy and self-esteem. Therefore, have the patient/family member/caregiver help keep a record of intake when possible. This often serves as a motivating factor to increase fluid intake. Offer support, understanding, and encouragement in providing nursing care because forcing fluid intake for the person experiencing no thirst can be uncomfortable.

Increasing the fluid intake of patients is a common nursing intervention. Use creativity to assist the patient and family/caregiver to reach desired goals. Having a tea party may be a helpful strategy to use when encouraging a child to increase fluids. When determining the patient's increased fluid intake, be sure to include fluids replaced through nasogastric, gastrostomy, or jejunostomy tubes in the fluid balance summary.

RESTRICTING FLUIDS

Restricting the patient's fluid intake is sometimes necessary. A prescribed intervention to decrease or restrict fluids indicates the amount of fluid the patient is to have in each 24-hour period.

Several interventions can be implemented to help patients restrict their intake of fluids. As with the method for increasing fluids, begin by explaining to the patient in understandable terms the rationale for the fluid restriction and the specified daily amount of fluid prescribed. Then work with the patient to develop short-term outcomes for accomplishing the overall task. Discuss with the patient the time intervals at which fluids will be served. Usually, offering fluids at 1- or 2-hour intervals and between meals is best because food often helps to relieve some feelings of thirst. Provide the fluid in small glasses or cups so that the container appears to contain more fluid than it actually does. Using ice chips also is helpful. Ice chips are about twice the volume of water in its liquid state and help to quench thirst. Remember to include the ice chips as part of the patient's fluid intake. If appropriate, encourage the patient/family member/caregiver to participate in their care by helping to keep a record of intake.

Consider **Mr. Park**, the patient who received too much IV fluid. As a result of this excess fluid intake and his subsequent development of problems, the nurse would be alert to the possibility that fluid restriction may be appropriate. If this occurs, the nurse needs to ensure that Mr. Park understands the reason for the restriction.

Patients who need to restrict fluid intake often report thirst or dry mouth. Avoid offering patients dry, salty, or sweet foods and fluids because such items tend to increase thirst. Also, attempt to divert the patient's attention from thirst by involving the patient in activities, and keep fluids not intended for the patient out of sight. Provide understanding, support, and encouragement because limiting fluid intake is uncomfortable for a thirsty person.

Provide oral hygiene at regular intervals so that the patient's mouth remains clean and moist. Lubricate the lips and mucous membranes as indicated. If the patient is capable, allow the patient to rinse the mouth with water without swallowing the fluid, to avoid exceeding the intake limit. If appropriate, the patient could try chewing sugar-free gum or sucking on sugar-free hard candy to stimulate the flow of saliva (MFMER, 2017).

Just as with fluid increases, fluid limits should also have shift totals set. This prevents one shift from taking all of the patient's allotted fluid and prepares the patient ahead of time for the fluid limits.

Administering Medications

Patients with fluid, electrolyte, and acid–base imbalances are often prescribed medications as part of the therapeutic regimen. Be knowledgeable about and understand the therapeutic effects of mineral–electrolyte preparations and diuretics and appreciate the potential risk for life-threatening adverse effects. It is also important to consider the impact of other medications, such as steroids and hormone replacements, on fluid and electrolyte balance.

MINERAL–ELECTROLYTE PREPARATIONS

Mineral–electrolyte preparations are frequently prescribed to correct electrolyte imbalances. Nursing responsibilities include:

- Accurate administration of the medications, following the manufacturer's guidelines; for example, diluting potassium supplements to disguise the unpleasant taste and decrease gastric irritation, or monitoring ABGs for increased pH after each 50 to 100 mEq of sodium bicarbonate to avoid overtreatment and metabolic alkalosis.
- Understand the intended therapeutic effect and evaluate the effectiveness of the therapy through patient assessment; for example, when administering magnesium sulfate, assessing for decreased restlessness and irritability, decreased muscle tremors, and control of convulsions.
- Assess for adverse effects; for example, when administering solutions containing sodium chloride, observe for hypernatremia.
- Understand and appreciate the risks associated with administration and the appropriate precautions to avoid adverse outcomes; for example, never administering IV potassium via IV bolus or carefully monitoring the infusion rate for IV potassium chloride solutions. The maximum rate should not exceed 10 mEq/hr (Adams et al., 2020). An administration error can result in sudden hyperkalemia, leading to a fatal cardiac arrhythmia.
- Assess for drug interactions; for example, consider drugs that increase the effects of minerals and electrolytes include acidifying agents, alkalinizing agents, cation exchange resin, iron salts, and potassium salts. Some minerals and electrolytes will enhance the effects of other medications, such as muscle relaxants.
- Teach patients about their prescribed mineral and electrolyte preparations and associated self-care behaviors.

DIURETICS

Diuretics are drugs that increase renal excretion of water, sodium, and other electrolytes. Although helpful in treating patients with FVE, they increase the risk for fluid volume deficit and serious electrolyte deficiencies. Careful monitoring of fluid intake, urine output, and serum electrolytes is essential for patient safety. Direct particular attention toward the patient's serum potassium level. It is important to provide patient education to any patient receiving diuretic therapy, including the rationale for the therapy, precautions, and side effects.

Administering Intravenous Fluid Therapy

The infusion of intravenous (IV) solutions may be prescribed to address fluid and/or electrolyte disturbances. The specific type and volume of solution to be administered is identified by the prescriber. The nurse is responsible for initiating, monitoring, and discontinuing the therapy. The nurse is also responsible for critically evaluating the prescribed intervention prior to administration. Any concerns regarding the type or amount of therapy prescribed should be immediately and clearly communicated to the prescribing practitioner. For example, if a patient's potassium level is noted to be elevated and the patient is prescribed a potassium-containing IV solution such as lactated Ringer's, the nurse should notify the prescribing practitioner of the laboratory result and request a revision of the prescribed intervention.

As with other therapeutic agents, the nurse must understand the rationale for the use of IV therapy for each patient, the type of solution being used, its desired effect, and potential adverse reactions. The contents of selected IV solutions and comments about their use are listed in Table 41-7 on page 1694.

Think back to **Grace Gilligan**, the woman with nausea and vomiting. The nurse could expect that this patient is high risk for fluid and electrolyte imbalances. What would be benefits and risks of administering the various IV solutions in Table 41-7 (on page 1694) to this patient? How would you assess if the IV therapy were having its desired effect (improving the patient's condition)?

EQUIPMENT

Sterile technique must be observed when accessing a vein to avoid possible catheter-related infection. Disposable infusion tubing and needles are used to help eliminate many possible sources of contamination and to reduce the cost of equipment aftercare.

Equipment used to administer IV fluid therapy varies according to the manufacturer. Be familiar with the equipment used in the facility or home setting. Typically, most solutions for infusions are dispensed in 1-L or 500-mL flexible or rigid plastic containers. Because plastic bags collapse under atmospheric pressure as the solution enters the patient's vein, they do not require a vent for air to enter to replace fluid flowing from the container. Small 50-, 100-, and 250-mL solution bags are available to administer intermittent IV medications (such as antibiotics given by IV piggyback).

Some medications bond with the plastic in IV bags. Therefore, glass bottles are required for these medications. Glass bottles do not collapse under atmospheric pressure and thus require a vent to allow air to enter the bottle as the fluid leaves the bottle.

IV administration tubing is used to attach the IV container to the patient's venous access. A basic administration set is illustrated in Figure 41-10 on page 1694. An IV administration set includes a spike or piercing pin to access the IV container, a drip chamber for observing fluid drops, a slide clamp to stop fluid flow, a roller clamp to manually regulate the rate of flow, a filter, several injection ports for administration of medications or additional IV fluids, and a connector at the end of the tubing to connect with the venous access (preferably Luer lock design, with threads that securely screw on) (refer to Fig. 41-10 on page 1694). Electronic infusion devices (infusion pumps) usually require tubing specific for the device; this tubing shares many of the same features as tubing used for gravity infusion. Tubing for an electronic infusion device also includes a mechanism that fits into the electronic device to control the infusion rate. Figure 41-11 (on page 1695) provides an example of an electronic infusion device.

Table 41-7 Selected IV Solutions

SOLUTION	COMMENTS
Isotonic Solutions	
Total osmolality close to that of the ECF; replace the ECF	
0.9% NaCl (normal saline)	Not desirable as routine maintenance solution because it provides only Na^+ and Cl^-, which are provided in excessive amounts. May be used to expand temporarily the extracellular compartment if circulatory insufficiency is a problem; also used to treat hypovolemia, metabolic alkalosis, mild hyponatremia, hypercalcemia. Used with administration of blood transfusions
Lactated Ringer's solution	Contains multiple electrolytes in about the same concentrations as found in plasma (note that this solution is lacking in Mg^{2+}) Used in the treatment of hypovolemia, burns, and fluid lost from GI sources
Hypotonic Solutions	
Hypotonic to plasma; replace ICF	
0.33% NaCl (1/3-strength normal saline)	Provides Na^+, Cl^-, and free water Na^+ and Cl^- allow kidneys to select and retain needed amounts Free water desirable as aid to kidneys in elimination of solutes Used in treating hypernatremia
0.45% NaCl (½-strength normal saline)	A hypotonic solution that provides Na^+, Cl^-, and free water Used as a basic fluid for maintenance needs Often used to treat hypernatremia (because this solution contains a small amount of Na^+, it dilutes the plasma sodium while not allowing it to drop too rapidly)

Hypertonic Solutions	
Hypertonic to plasma	
5% dextrose in lactated Ringer's solution	Supplies fluid and calories to the body Replaces electrolytes; shifts fluid from the intracellular compartment into the intravascular space, expanding vascular volume
5% dextrose in 0.9% NaCl	Used to treat SIADH Can temporarily be used to treat hypovolemia if plasma expander is not available

FIGURE 41-11. An electronic infusion device. (*Source:* Used with permission from Shutterstock. *Photo by Rudy Umans*.)

A variety of needles and catheters are commonly used for peripheral IV infusions. IV catheters are plastic tubes that have been mounted on a needle or are threaded through a needle for insertion. Once inserted, the needle is withdrawn, and the flexible catheter remains in the vein. The over-the-needle catheter is easy to insert and stable. Single- or double-winged infusion needles (butterflies) are short-beveled, thin-walled needles with plastic flaps and are not flexible, and thus are more likely to infiltrate. They may be used with single-dose administration (Gorski et al.,

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

2021). Refer to the vascular access devices discussion in the next section. Other equipment necessary to start an IV infusion is listed in Skill 41-1 (on pp. 1715–1724).

Many devices are available that minimize the potential for injury and promote safety when connecting, accessing, or disposing of IV equipment, including needleless systems and needle-housing systems in which the needle is recessed and protected. Luer-locking (with threads that securely screw on) needleless connectors are used to connect syringes and/or administration sets to a vascular access device hub or other injection site and should be included as part of vascular access device policies and procedures. The primary purpose of needleless connectors is to protect health care personnel by eliminating needles and reduce associated needlestick injuries when attaching administration sets and/or syringes to the vascular access device (Gorski et al., 2021). A short extension tubing set is often used between the venous access device and the needleless connector to reduce catheter manipulation (Gorski et al., 2021). Closed-system peripheral intravenous catheters integrate the catheter and extension tubing as one piece (Galang et al., 2020), eliminating the need for the addition of separate extension tubing. It is important to follow the manufacturers' recommendations for appropriate sequencing of clamping and final syringe disconnection when flushing and/or using the connector to reduce the amount of blood reflux into the venous access device lumen and subsequent potential occlusion of the venous access device from intraluminal thrombosis (Gorski et al., 2021). Figure 41-12 provides an example of a PIVC with short extension tubing, venous catheter stabilization device, and a needleless connector in place. Additional information regarding needleless connectors is discussed later in the chapter. Additional information regarding closed or closed peripheral intravenous catheters is discussed in the following section.

FIGURE 41-12. A peripheral venous access device with short extension tubing and a needleless connector.

Refer to Chapter 30 for additional information about protective measures and use of IV equipment related to medication administration.

VASCULAR ACCESS DEVICES

Many different options for vascular access devices (VADs) are available for delivery of solutions and medications into a vein. The length of time the infusion therapy is needed, the type of medication or product that will be delivered intravenously, the patient's vascular condition, and the patient's health status as well as individualized needs determine which option is used (Gorski, et al., 2021). In addition, decisions on insertion site and catheter type should also be guided by what will pose the least risk for IV complications (Gorski et al., 2021; Higginson, 2015; Moureau & Chopra, 2016). Guidelines from the Infusion Nurses Society recommend selection of the least invasive VAD with the smallest outer diameter and fewest number of lumens needed for the prescribed therapy (Gorski et al., 2021). The nursing care that is required will depend on the type of device or IV catheter that is utilized. Vascular access devices include peripheral venous catheters, midline catheters, and central venous access devices (CVADs).

Peripheral Venous Catheters

Peripheral intravenous catheters (PIVCs) are inserted into and reside in veins of the periphery that include all extremities, the external jugular vein and scalp veins in neonates (Gorski et al., 2021). These over-the-needle catheters are the most common type of peripheral vascular catheter used: *short PIVCs* are inserted into superficial veins; *long PIVCs* are inserted in either superficial or deep peripheral veins and are an option when a short PIVC is not long enough to adequately cannulate the available vein, or the vessel is difficult to palpate or visualize with the naked eye (Gorski et al., 2021). When the anticipated duration of infusion therapy will be brief (less than 4 days [Gorski et al., 2021]), a short (<3 inches) peripheral catheter is placed in a peripheral vein (see Fig. 41-12 on page 1695). The tip of a short peripheral catheter terminates in the peripheral vein. This device is not appropriate for certain therapies, such as vesicant chemotherapy, drugs that are classified as irritants, or PN (Gorski et al., 2021).

When the anticipated duration of infusion therapy in hospitalized patients will be 5 to 14 days and peripheral infusion is appropriate, insert a *midline catheter* (Gorski et al., 2021; O'Grady et al., 2017). Midline catheters are inserted peripherally into the upper arm into the basilic, cephalic, or brachial veins. These catheters are longer (>3 inches) than peripheral venous catheters, and the distal tip terminates in the basilic, cephalic, or brachial vein, at or below the axillary level and distal to the shoulder (Gorski et al., 2021). In neonates, midline catheters may also be inserted into a scalp vein with the distal tip located in the jugular vein above the clavicle or in the lower extremity with the distal tip located in the inguinal crease (Gorski et al., 2021). Midlines are not considered to be central lines and should not be used to continuously infuse vesicants, solutions with extremes of pH or osmolarity, or PN (Gorski et al., 2021). Use of midlines should also be avoided for patients with a history of thrombosis, hypercoagulability, decreased venous flow to the extremities, or end-stage renal disease (Gorski et al., 2021).

The smallest-gauge device that will accommodate the prescribed therapy and patient need should be selected (Gorski et al., 2021) (see Chapter 30 for more discussion on gauges). A 20- to 24-gauge catheter is recommended for most infusions to decrease the risk of phlebitis; a 22- to 26-gauge catheter is recommended for neonates, pediatric patients, older adults, and patients with limited venous options to minimize insertion-related trauma (Gorski et al., 2021). In inpatient and nursing facilities, the PIVC insertion site, site dressing and securement device should be assessed every 4 hours at a minimum (Gorski et al., 2021). In community-based settings, assess the PIVC at every visit and teach the patient/family member/caregiver to check the site at least once per day or every 4 hours during waking hours for continuous PIVC infusions (Gorski et al., 2021).

Previously, recommendations suggested routine rotation of insertion sites at various intervals, usually 72 to 96 hours. Current research and guidelines support maintaining peripheral IV access devices until no longer clinically indicated (discontinuation of infusion therapy; not used for 24 hours or more; no longer included in plan of care) or until there is an unresolved complication (presence of site complication [e.g., phlebitis, infiltration, extravasation] or systemic complication [e.g., infection]) (Bolton, 2015; Gorski et al., 2021; Loveday et al., 2014; Tuffaha et al., 2014). Nurses should use clinical assessment and judgment in deciding when to replace or discontinue a peripheral IV catheter. The clinical need for the IV catheter should be assessed on a daily basis in acute inpatient settings and during regular assessment visits in community-based care settings (Gorski et al., 2021).

Central Venous Access Devices

Central venous (vascular) access devices (CVADs) are an integral component of patient care in acute, ambulatory, and subacute care settings, as well as in the home and long-term care facilities. They provide access for a variety of IV fluids, medications, blood products, and PN solutions and allow a means for hemodynamic monitoring and blood sampling. The use of a CVAD should be considered when the anticipated duration of infusion therapy is >15 days (Gorski et al., 2021). The type and duration of infusion therapy, patient preference, the patient's physiologic condition (age, health problems, comorbidities), and the patient's vascular condition (history of vascular access attempts, vessel and skin health at potential insertion sites) determine the type of CVAD used (Gorski et al., 2021). The tip of the CVAD catheter terminates in the central venous circulation, usually in the lower one third of the superior vena cava near its junction with the right atrium (Gorski et al., 2021). The use of ultrasound technology during insertion by a practitioner fully trained in its technique is recommended if available to increase success rates and decrease insertion-related complications (Gorski et al., 2021; O'Grady et al., 2017). **All CVADs require radiographic confirmation of position after insertion and before use** (Gorski et al., 2021). Some CVADs have more than one lumen to allow for multiple concurrent infusions; a CVAD with the minimum number of lumens essential for the management of the patient should be used (O'Grady et al., 2017). The individual patient circumstances and plan of care may result in use of the CVAD for a relatively short period of time or a longer period of time, perhaps years. Insight into the patient experience of living with a CVAD can help nurses provide appropriate support for these patients. Refer to the accompanying Research in Nursing box.

Types of CVADs include the following:

- Peripherally inserted central catheter (PICC)
- Nontunneled percutaneous central venous catheter
- Tunneled percutaneous central venous catheter
- Implanted port

PICCs are a type of CVAD (>20 cm depending on patient size; single or double lumen) that can be introduced into a peripheral vein (the basilic, brachial [preferred], or cephalic veins) above the antecubital fossa (Gorski et al., 2021) (Fig. 41-13). A specially trained registered nurse or other advanced practice professional can insert this type of catheter. A PICC may be inserted in interventional radiology units or, in some institutions, at the bedside. PICCs may have single or multiple lumens. They are used extensively in the home for IV therapy and have become an increasingly common venous access device in acute-care settings, especially for patients requiring long-term IV therapy (6 weeks to 6 months). Indications for use of PICCs include administration of IV antibiotics for an extended period (>1 week), infusion of parenteral nutrition, chemotherapy and other targeted therapy drugs, continuous pain management infusions, vesicants, hyperosmolar solutions, blood components, other specific medications (e.g.,

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

vasopressors, anticoagulants), and long-term rehydration. Advantages of using a PICC include that it can remain in place for an extended period of time (6 months to a year or 18 months if no complications arise) and for obtaining blood samples (Memorial Sloan Kettering Cancer Center, 2021). In addition, because the catheter is inserted peripherally, PICCs may be associated with less risk of complications than other CVADs, such as nerve damage, stenosis, and pneumothorax (Moureau & Chopra, 2016).

Research in Nursing

Bridging the Gap to Evidence-Based Practice

Central Venous Access Devices and Patients' Experiences

Central venous access devices (CVADs) have become an increasingly common in community settings for IV therapy, venous access for blood sampling, especially for patients requiring long-term IV therapy, such as chemotherapy and antibiotics. The use of a CVAD requires patients to make adjustments in daily life situations, such as showering, washing hair and sleeping; possible alterations in body image; and caring for the CVAD. What are patients' experiences of living with a CVAD?

Related Research

Kelly, L., & Snowden, A. (2021). 'Pinholes in my arms': The vicious cycle of vascular access. *British Journal of Nursing*, *30*(14), S4–S13. https://doi.org/10.12968/bjon.2021.30.14.S4

The aim of this qualitative study was to explore how patients make sense of living with a CVAD and to explore the experiences of living with an external or implanted vascular access device. Participants were purposefully recruited from a cancer treatment center in Scotland. Patients who had a CVAD in place for longer than 3 weeks were eligible to participate. Eleven patients responded to the recruitment request, and all were enrolled; 5 participants had a PICC, 3 had a tunneled CVAD, and 3 had an implanted CVAD. One-to-one semi-structured interviews were performed and were recorded. The interviews were transcribed verbatim and analyzed. Four superordinate themes, some with subthemes, were identified by the authors, including *The self under attack (subthemes: the violation of vascular access; accepting the ordeals of vascular access), Being rescued/being robbed (subthemes: being thrown a lifeline, device as part of self, better than the rest), Protection of others/protection of self,* and *Bewilderment and dismay at lack of staff competence*. The authors presented a resulting conceptual framework of the "vicious cycle of vascular access." The authors concluded having a CVAD affects the psychological, social, and personal self; impacts on self-esteem and self-image; and that the results suggest that CVADs are accepted by patients and are, in the end, embodied by them.

Relevance to Nursing Practice

Nurses are a key source of support for patients and can provide information, guidance, and support to assist patients in managing life with a CVAD. Nurses should consider patient experiences when developing a plan of care to improve quality of life and support optimal patient outcomes.

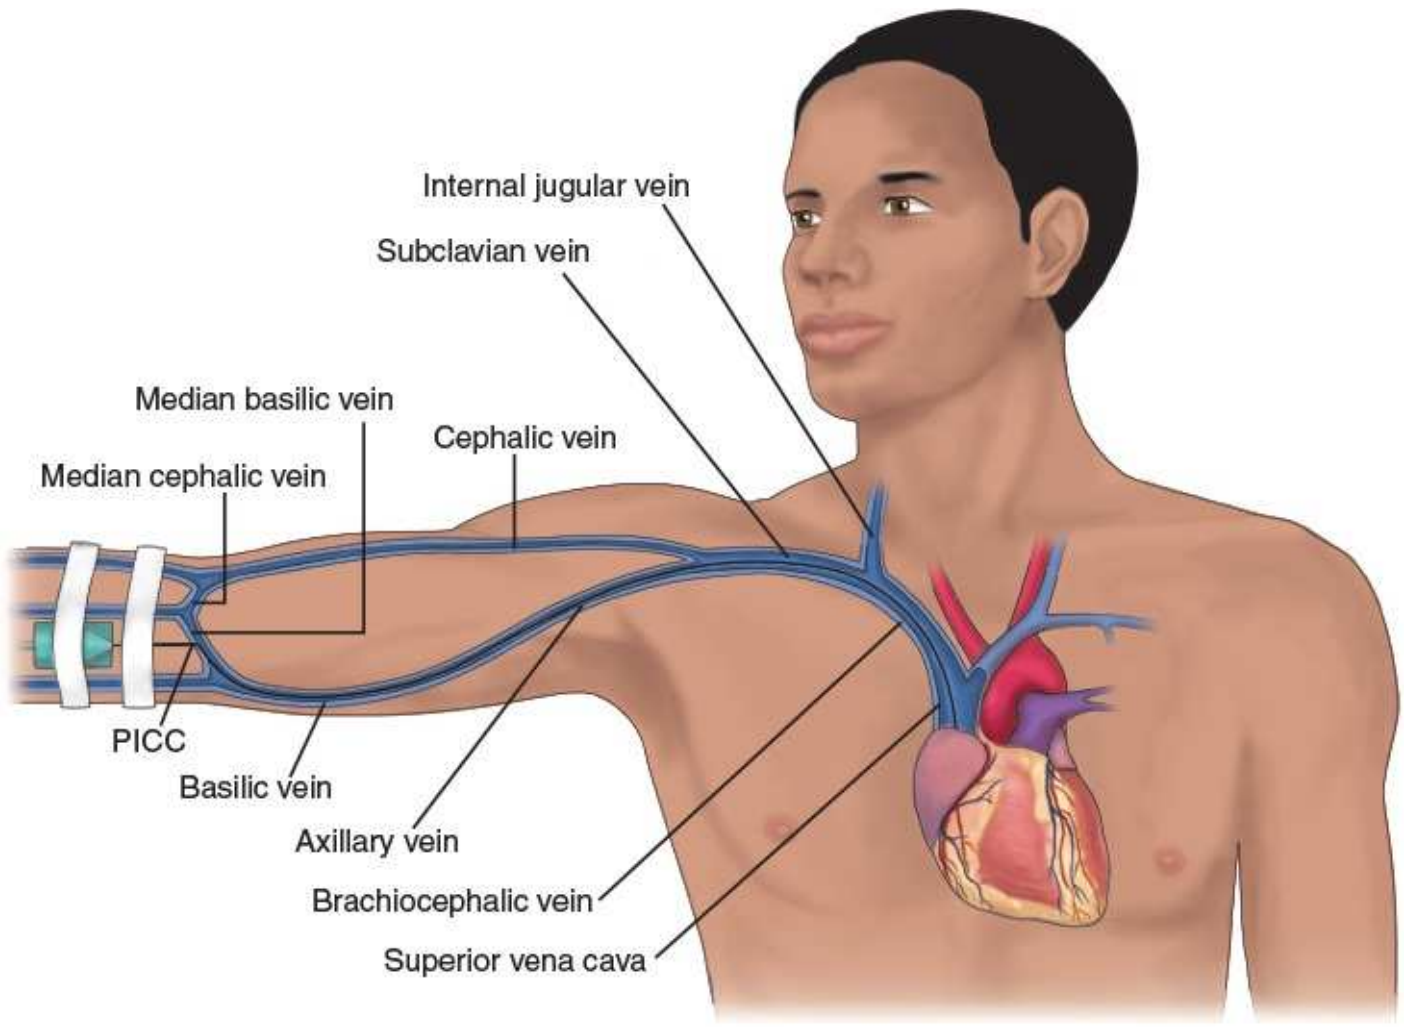

FIGURE 41-13. Placement of a peripherally inserted central catheter (PICC).

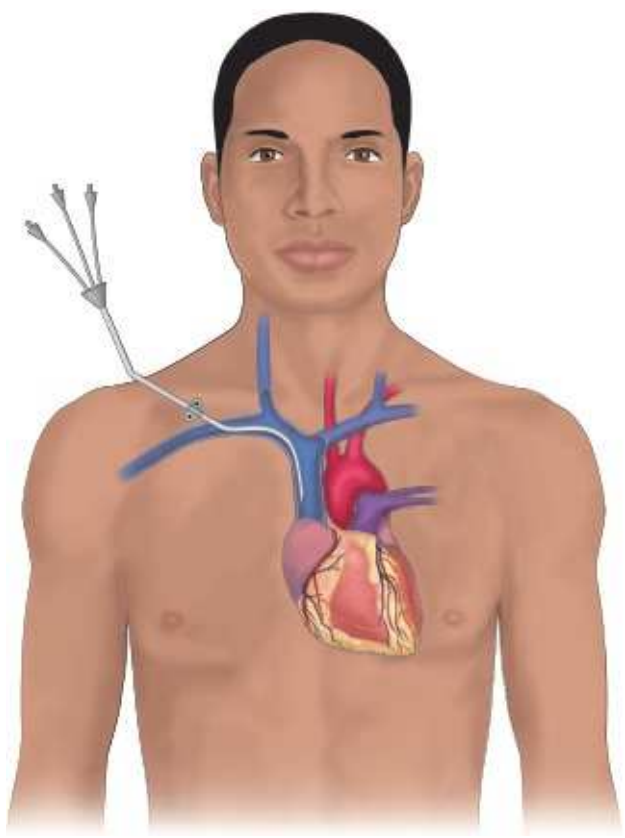

FIGURE 41-14. Placement of a triple-lumen nontunneled percutaneous central venous catheter.

Nontunneled percutaneous central venous catheters (Fig. 41-14) have a shorter dwell time (<14 days). These catheters can have double, triple, or quadruple lumens and are >8 cm, depending on patient size. They are introduced through the skin into the internal jugular, subclavian, or femoral veins. Catheters inserted via the femoral vein should have the distal tip dwell in the thoracic inferior vena cava above the level of the diaphragm (Gorski et al., 2021). They are mainly used short-term critical access with patients who are unstable (Moureau & Chopra, 2016); the CDC recommends avoiding the femoral vein for central venous access in adult patients (O'Grady et al., 2017). Pneumothorax is a potential complication when the catheter is placed in the subclavian vein.

A *tunneled central venous catheter* is implanted into the internal or external jugular or subclavian vein and intended for long-term use. The length of this catheter is >8 cm (approximately 90 cm, on average), depending on patient size, and is tunneled in subcutaneous tissue under the skin (usually the midchest area) for 3 to 6 inches to its exit site (Fig. 41-15). This device is initially sutured into place, but after 7 to 14 days, the sutures are usually removed. Subcutaneous tissue attaches to a Dacron polyester cuff around the catheter, helping to stabilize the catheter and minimize the risk for infection. Once the exit site is healed, a site dressing is not required. This type of catheter is associated with a lower incidence of infection than is the nontunneled central venous catheter (O'Grady et al., 2017).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

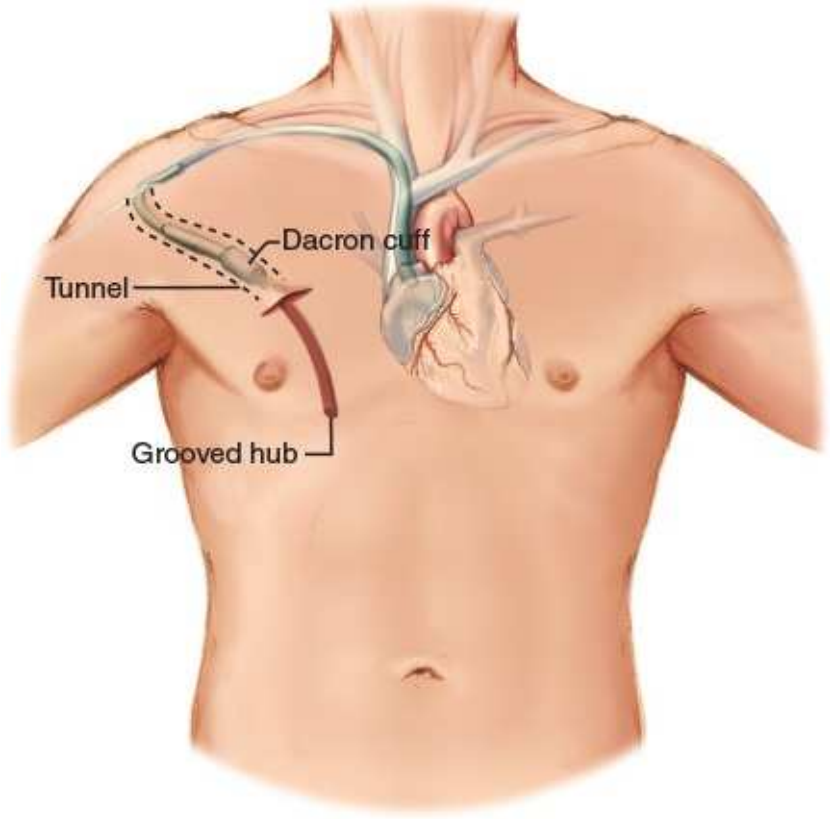

FIGURE 41-15. Placement of a tunneled central venous catheter.

Another type of long-term CVAD is an *implanted port*, which consists of a subcutaneous injection port attached to a catheter. The distal catheter tip dwells in the lower segment of the superior vena cava at or near the cavoatrial junction (CAJ) and the proximal end or port is implanted in a subcutaneous pocket of the upper chest (typical) or abdominal wall. Implanted ports placed in the upper arm (or less commonly, lower extremity) are referred to as *peripheral access system ports*. Implanted ports have a lower rate of infection compared to tunneled and nontunneled CVADs; have a low risk of complication during treatment, require minimal care and management by the patient, and may be associated with improved body image (Gorski et al., 2021; Kline & Katrancha, 2019; O'Grady et al., 2017). When not in use, no external parts of the system are visible. A special angled noncoring needle is inserted through the skin and rubber septum and into the port reservoir to access the system (Fig. 41-16). Implanted ports require minimal care, but the discomfort related to accessing the port may be a disadvantage for some patients. Surgery is required for catheter removal (O'Grady et al., 2017).

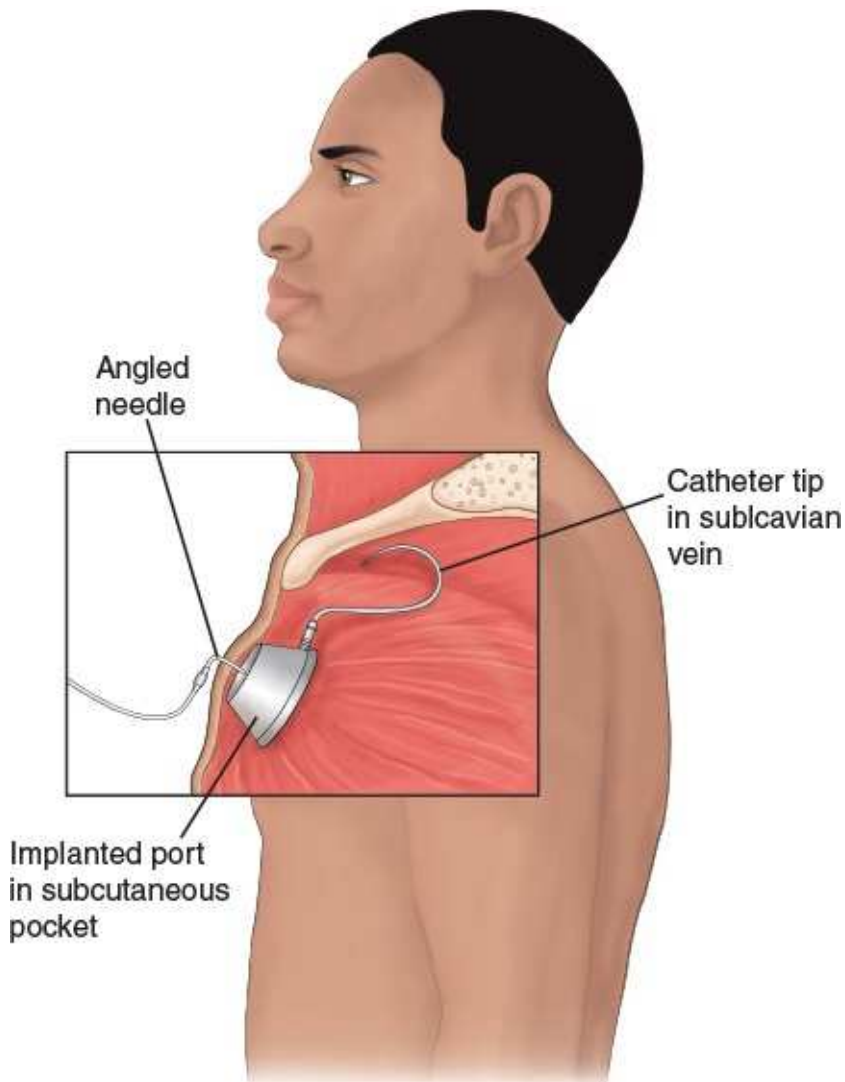

FIGURE 41-16. Placement of an implanted port with the tip in the subclavian vein. An angled needle is inserted through the skin and septum into the port.

In inpatient and nursing facilities, assess the CVAD insertion site, site dressing, and securement device with each

infusion and at least daily (Gorski et al., 2021). In community-based settings, assess the CVAD at every visit and teach the patient/family member/caregiver to check the site with each infusion or at least once per day (Gorski et al., 2021). CVADs are not routinely changed in order to reduce the risk of infection (O'Grady et al., 2017). However, any central venous catheter may be removed and/or replaced if suspicion of a catheter-related bloodstream infection or other complication exists. CVAD-related complications include thrombosis, central line–related bloodstream infection (CLABSI), air embolism, phlebitis, and occlusion (Berndt & Steinheiser, 2019; Gorski et al., 2021; McArthur, 2018; Walters & Price, 2019). The continued need for *PICCs* and *nontunneled* CVADs should be assessed on a daily basis and removed when there is a change in the patient's infusion needs or it is no longer needed for the plan of care (Gorski et al., 2021). The continued need for *tunneled* and *implanted* CVADs should be assessed on a regular basis; removal may be indicated when infusion therapy is completed, in the presence of an unresolved complication, or when it is no longer needed for the plan of care; consideration should be given to the possibility for infusion therapy to resume in the future (Gorski et al., 2021).

PERIPHERAL VASCULAR ACCESS CONSIDERATIONS

The nurse initiating a PIVC needs to assess for the safest, most appropriate site for each particular patient. The suitability of particular veins for peripheral IV infusions varies with individual circumstances. The accessibility and condition of the vein and the type of fluid to be infused should be considered when determining the location for intravenous access via a PIVC. Measures to increase insertion success, including consideration of vascular visualization technology and management of insertion pain, should be implemented.

Accessibility of a Vein

Keep in mind the following guidelines related to PIVCs and access sites:

- Discuss the preference for VAD site selection with the patient/family/caregivers (Gorski et al., 2021).
- Determine the most desirable accessible vein. For a short PIVC, use the forearm to prolong dwell time, increase the likelihood of the PIVC lasting the full length of the prescribed therapy, decrease pain during dwell time, promote self-care, and prevent accidental removal and occlusions (Gorski et al., 2021). The dorsal and ventral surfaces of the upper extremities, including the metacarpal, cephalic, basilic, and median veins, are appropriate sites for infusion (Gorski et al., 2021). Avoid the cephalic vein at the radial wrist, inner aspect of the wrist, and sites at/above the antecubital fossa because of the potential risk for nerve damage (Gorski et al., 2021). Figure 41-17A illustrates infusion sites on the arm and hand for adult patients. For a long PIVC, use the veins on the dorsal and ventral surfaces of the upper extremities, including the cephalic, basilic, and median veins; insertion should be in the forearm without crossing into the antecubital fossa (Gorski et al., 2021). Consider use of the basilic, cephalic, or brachial veins when inserting a midline catheter (Gorski et al., 2021).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

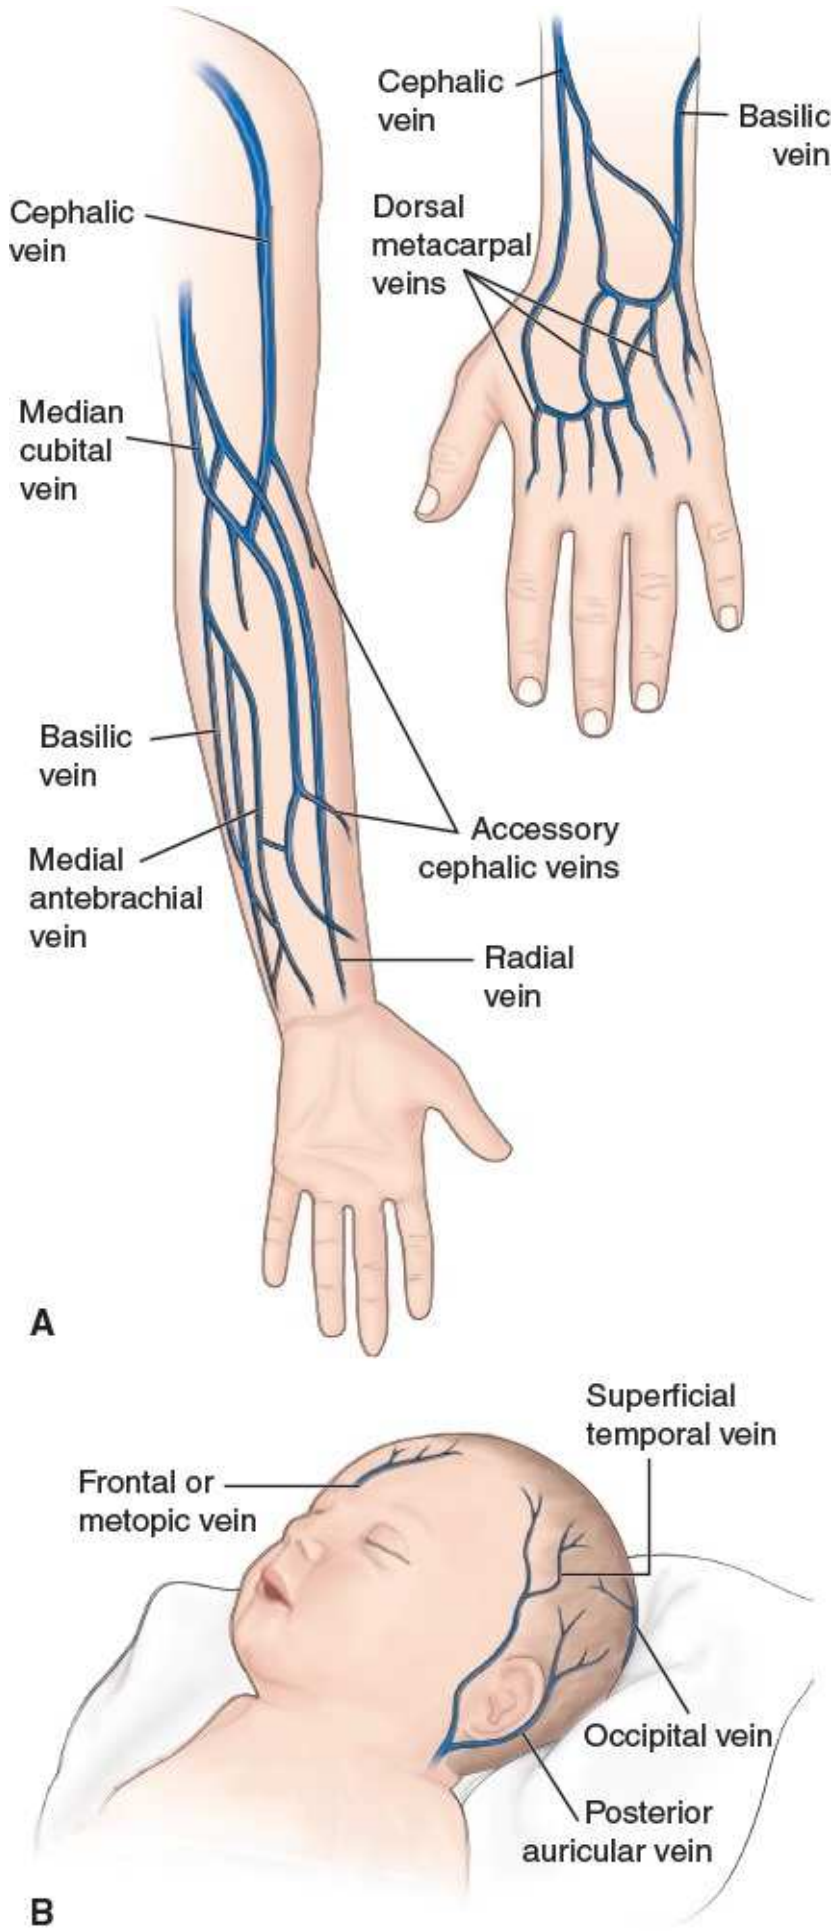

FIGURE 41-17. Peripheral venous access sites. **A.** Infusion sites on the ventral and dorsal aspects of the lower arm and hand. **B.** Infusion sites on the scalp of an infant.

- In general, either arm may be used for IV therapy. Use of the nondominant arm is preferred for patient comfort and to limit movement in the impacted extremity (Gorski et al., 2021). For example, if the patient is right-handed, the IV is preferably placed on the left extremity to improve the patient's ability to complete activities of daily living. This is particularly important if the duration of infusion is expected to be prolonged.
- In adults, hand veins may be considered for short-term therapy (>24 hours); catheter insertion in areas of flexion such as the hand is associated with higher failure rates over time (Gorski et al., 2021).
- The use of an extremity for IV therapy may be contraindicated in some circumstances. For example, patients with a history of breast cancer with same-side surgical axillary lymph node removal; patients with burns, infections, or traumatic injury to the extremity; and patients with upper extremity arteriovenous fistulas or catheters for dialysis treatment will not be able to have an IV catheter placed on the impacted extremity.
- Avoid PIVC insertion in areas of flexion; pain on palpation; compromised skin and sites distal to these areas (such as open wounds); extremities with infection; extremities with planned procedures (Gorski et al., 2021).
- Do not use the antecubital veins if another vein is available. They are not a good choice for infusion because flexion of the patient's arm can displace the IV catheter over time. In addition, by avoiding the antecubital veins for peripheral venous catheters, a PICC line may be inserted at a later time, if needed.

- Do not use veins in the leg of an adult, unless needed for an emergent insertion, and if used, remove as soon as possible; use of the lower extremities is associated with risk of tissue damage, thrombophlebitis, and ulceration (Gorski et al., 2021). Some facilities require a prescribed intervention to insert an IV catheter in an adult patient's lower extremity.
- Neonates and pediatric patients: Potential sites for short PIVCs include veins in the hand, forearm, and if not walking, the foot; avoid the antecubital fossa, which has a higher failure rate (Gorski et al., 2021). When no alternative site is available, veins of the scalp may be used as a last resort; avoid the use of the hands, thumbs, or fingers (Gorski et al., 2021). Scalp arteries in infants are visible (see Fig. 41-17B). Consider veins in the forearm and the saphenous vein for long PIVCs (Gorski et al., 2021). Select an upper arm site using the basilic, cephalic, or brachial veins; veins in the leg (saphenous, popliteal, femoral) with the tip below the inguinal crease; and in the scalp with the tip in the neck, above the thorax for placement of a midline catheter (Gorski et al., 2021).

Think back to **Grace Gilligan**, the patient with nausea and vomiting. The nurse would incorporate knowledge of appropriate site selection for adults when determining the location for Grace's venous access.

Condition of the Vein

The ability to assess the condition of the patient's vein and to determine the degree of difficulty for successful insertion of an IV access is an extremely important skill. Experience is necessary to perform these skills. Factors that may interfere with successful evaluation of the condition of the patient's veins and subsequent placement of a peripheral catheter include obesity, diabetes, hypertension, variations in skin between patient populations (e.g., darker skin tones, excessive hair, presence of scars or tattoos), increased patient age, neonates, fluid volume deficit, injection drug use, the presence of multiple chronic health conditions (e.g., diabetes, renal disease), vascular disease, chemotherapy, and/or frequent hospitalizations (Dougherty, 2013; Dychter et al., 2012; Fields et al., 2014; Gorski et al, 2021; Morata & Bowers, 2020; Partovi-Deilami et al., 2016). These factors interfere with use of traditional techniques of direct visualization, anatomic landmarks, and palpation and make placement of PIVC difficult (Gorski et al., 2021; Houston, 2013). In addition, thin-walled and scarred veins, common in older adults, are fragile and prone to infiltration, which can make continued infusion a problem. The size of the vein will also limit the maximum gauge (size) catheter that can be inserted. Insertion of a PIVC in areas of veins that are compromised, such as previous PIVC, bruised, reddened/streaked, infiltrated, sclerosed, and/or engorged should be avoided (Gorski et al., 2021).

Type of Fluid to Be Infused

The type of fluid to be infused should be considered when determining the location for intravenous access via a PIVC. Keep in mind the following about the type of IV fluid to be infused:

- Select a vein and IV catheter size appropriate for the solution. Hypertonic solutions, those containing irritating medications, those administered at a rapid rate, and those with a high viscosity (such as a blood transfusion) should be given in a large vein, ideally using a large-gauge IV catheter to minimize vessel trauma and to facilitate the rate of flow. A larger-gauge catheter should be considered when rapid fluid replacement is required (Gorski et al., 2021). Use a 20- to 24-gauge PIVC based on vein size for blood transfusion; a large-gauge PIVC is recommended when rapid transfusion is required (Gorski et al., 2021). Additional discussion about blood transfusion is provided later in the chapter.
- Advise the patient that some medications administered intravenously in a peripheral vein (e.g., potassium chloride and certain antibiotics) may cause irritation and pain. Use of short PIVCs for continuous infusion of medication with irritant or vesicant properties should be avoided (Gorski et al., 2021). Educate the patient about the need to immediately report any discomfort to allow for timely intervention.

Measures to Increase PIVC Insertion Success

Measures to increase insertion success should be implemented. An individual nurse should not make more than two attempts at vascular access placement when initiating venous access for a patient (Gorski et al., 2021). If unsuccessful after two attempts, a colleague with advanced skills, such as a member of the nurse IV team, should attempt to initiate

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

the venous access (Gorski et al., 2021). Multiple unsuccessful attempts cause pain to the patient and result in delayed treatment, limited future vascular access, increased costs, and increased risk for complications (Gorski et al., 2021). Use of vascular visualization technology may be appropriate after unsuccessful insertion attempts. Refer to the Reflective Practice box on page 1670.

QSEN TEAMWORK AND COLLABORATION

Nurses have a responsibility to function effectively within nursing and interprofessional teams, recognizing the contributions of others to achieve quality patient care. The nurse should collaborate with other members of the health care team and the patient to discuss appropriate options for a patient with difficult vascular access (Gorski et al., 2021; O'Grady et al., 2017).

Assess the patient's health history and current health status to identify factors that may affect the peripheral vasculature and increase difficulty with locating veins by observation. Refer to the previous discussion about vein condition on page 1700. Vascular visualization technology can be used to assist with identification of peripheral veins, with resulting increased insertion success, reduced insertion-related complications, and minimization of the need to escalate to unnecessary, more invasive venous access devices (Gorski et al., 2021). Visible light devices are one technology that can aid in locating superficial veins in neonates, but their usefulness in infants, older children, and adults is limited due to the thickness of subcutaneous tissue and the size of the arm circumference (Çağlar et al., 2019; Gorski et al., 2021; Gümüs & Başbakkal, 2021; Heinrichs et al., 2013; Pitts & Ostroff, 2019). Another vascular visualization technology is near infrared light (nIR). This technology uses infrared light to capture an image of veins and reflect it back to the skin surface or to a screen The use of nIR provides information is recommended to make more informed decisions about vein selection, decreases procedure time for PIVC insertion, and is associated with enhanced first-time insertion success in some patient, such as neonates (Gorski et al., 2021).

Ultrasound is another visualization technology to guide peripheral IV placement. Ultrasound-guided PIVC insertion is a safe, efficient intervention and should be used for placement of short PIVC in difficult-to-access adult patients (Gorski et al., 2021; Houston, 2013), the insertion of long PIVCs (Gorski et al., 2021), and after failed venipuncture attempts (Edwards & Jones, 2018; Egan et al., 2013). Images produced by ultrasound offer a visual advantage for locating the best peripheral veins to access as well as direct measurement of blood vessel diameter and condition (Arbique et al., 2014; Gorski et al., 2021). Use of ultrasound to guide placement also allows visualization of the IV catheter tip inside the vein and verification of placement of the catheter (Arbique et al., 2014). The use of ultrasound-guided PIVC placement has been associated with higher success rates; less time to cannulation; fewer needle sticks; decreased pain; decreased use of more invasive venous access devices, such as PICC and midline catheters; and longer survival time (time from placement to removal) (Desai et al., 2018; Galen et al., 2020; Houston, 2013; Moore, 2013; Vinograd et al., 2018).

Interventions to improve patient experience of PIVC insertion should include pain management strategies. Local anesthetic agents should be used to reduce pain in all adult and pediatric populations (Gorski et al., 2021). Local anesthetic agents to reduce pain associated with PIVC insertion include vapocoolant sprays, topical transdermal agents, jet injection of pressure-accelerated lidocaine (needle-free), application of hot or cold to the site, and intradermal injection of lidocaine or bacteriostatic 0.9% sodium chloride (Gorski et al., 2021; Korkut et al., 2020; Welyczko, 2020). The nurse needs to have knowledge of the anesthetic agent used and correct method of administration, based on the manufacturer's recommendations and facility policy. The use of a local anesthetic requires monitoring for potential allergic reactions, tissue damage, or inadvertent injection of the drug into the vascular system (Gorski et al., 2021). In addition, nonpharmacologic interventions should also be considered to reduce pain associated with PIVC insertion. Nonpharmacologic interventions suggested for use to reduce PIVC insertion-related pain and discomfort include distraction, relaxation, breathing exercises, local application of heat (Korkut et al., 2020), and virtual reality (VR) (Basak et al., 2020; Gorski et al., 2021). The choices of interventions for pediatric patients include swaddling, breastfeeding, pacifiers, rocking, blowing bubbles, reading books, VR, and local vibrating cold devices and should be made with consideration of growth and development level (Gorski et al., 2021).

Think back to **Grace Gilligan**, the patient who experienced several unsuccessful IV catheter insertion attempts, as described in the Reflective Practice box on page 1670. The nurse's ability to palpate the patient's veins before attempting venipuncture might have been helpful in determining the best vein to be used. The information provided by palpation also could have indicated that the patient's veins were scarred, thus suggesting the need for use of ultrasound to guide placement and/or the need for consultation with a more experienced team member, such as an IV nurse specialist (as the patient had requested) to perform the procedure.

INITIATION OF AN INTRAVENOUS INFUSION

Administration of IV solutions requires the same system of checks and rights of administration as for medication administration (refer to Chapter 30). Before the infusion is started, perform a final check of the solution to ensure that it is clear and contains no particles or precipitates. This check is especially important when substances have been added to the solution because some additives create precipitates. Commercially available in-line filters help reduce the risk for contamination by filtering the solution immediately before it enters the patient's vein. Skill 41-1 outlines the procedure for initiating a PIVC and an IV infusion (see p. 1715). Some adults and young children have a fear of needles and/or venipuncture. Provide information about the venipuncture process and infusion therapy procedures in an age-appropriate manner to decrease distress and anxiety (Gorski et al., 2021). Pharmacologic and nonpharmacologic interventions should be implemented to reduce anxiety and pain related to venipuncture. Refer to the discussion of pain management in the previous section (p. 1701).

INFUSION REGULATION AND MONITORING

The nurse is responsible for maintaining the proper IV infusion flow rate while ensuring the comfort and safety of the patient. IV fluid infusions are prescribed interventions, and the prescription identifies the amount of solution to be infused in a specified period of time. The nurse determines the infusion rate based on the amount of solution to be infused over 1 hour to achieve the prescribed infusion volume over the prescribed period of time. If the prescribed intervention is unclear in any way or does not seem appropriate based on the patient's condition and/or status, it is the nurse's responsibility to ask the prescribing practitioner for clarification prior to beginning administration. Maintenance of the flow rate is important because it can directly affect the patient's fluid balance. Too slow a flow may result in a fluid volume deficit because fluid intake is not balancing fluid lost or it may delay the restoration of the balance. Infusing IV fluid too rapidly can overtax the body's capacities to adjust to the increase in the water volume or the electrolytes it contains and may lead to FVE. Allowing an infusion to get behind schedule and then increasing the rate to catch up might seriously jeopardize the patient's compensatory mechanisms and lead to serious complications, such as in a patient with heart failure. Skill 41-2 (on pp. 1725–1727) discusses the monitoring of an IV infusion.

The use of electronic infusion pumps (IV pumps) is suggested best practice (Gorski et al., 2021) and is widely implemented as a standard of care in acute care settings to reduce infusion-related medication errors (ISMP, 2020). These devices can be programmed to infuse a certain amount of fluid over a given time, usually milliliters per hour. When using an electronic device, it is not necessary to calculate the drops per minute, as is necessary with a gravity or free-flowing IV infusion. The pump automatically regulates the flow rate at preset limits. An alarm sounds when air is in the tubing, the flow is obstructed, the solution level of the bottle or bag is getting low, or there is increased pressure in the system, such as occurs when a VAD infiltrates and fluid flows into the tissues. Smart pumps are IV infusion devices that provide computerized dose error-reduction software with IV therapy libraries and corresponding administration rate limits (ISMP, 2020). Smart pumps are used in more than 80% of hospital settings in the United States (ISMP, 2020). The Institute for Safe Medication Practices (ISMP, 2020) suggests "Smart pumps can provide a great deal of data that is useful in driving safe practices" (p. 3). Although the design of these pumps may enhance patient safety, it is important that nurses always remember that they are ultimately responsible for accurate programming of the pump and fluid administration. Check the infusion every hour or more frequently, if indicated, to determine if the solution is being infused at the proper hourly rate.

Guidelines for Nursing Care 41-2

Regulating Intravenous Flow Rate

Follow facility guidelines to determine if infusion should be administered by electronic infusion device or by gravity.

- Verify the prescribed IV solution.
- Check the patency of IV access.

If the infusion is to be administered by gravity infusion:

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Verify the drop factor (number of drops in 1 mL) of the equipment in use.
- Calculate the flow rate:

  EXAMPLE—Administer 1,000 mL D_5W over 10 hours (set delivers 60 drops/1 mL).

  a. **Standard formula**

$$\text{gtt (drops)/min} = \frac{\text{volume (mL)} \times \text{drop factor (gtt (drops)/mL)}}{\text{time (in minutes)}}$$

$$\text{gtt (drops)/min} = \frac{1{,}000 \text{ mL} \times 60}{600 \text{ (60 min} \times 10 \text{ h)}}$$

$$= \frac{60{,}000}{600}$$

$$= 100 \text{ gtt (drops)/min}$$

  b. Short formula using milliliters per hour

$$\text{gtt (drops)/min} = \frac{\text{volume (mL)} \times \text{drop factor (gtt (drops)/mL)}}{\text{time (in minutes)}}$$

$$\text{gtt (drops)/min} = \frac{1{,}000 \text{ mL} \times 60}{600 \text{ (60 min} \times 10 \text{ h)}}$$

$$= \frac{60{,}000}{600}$$

$$= 100 \text{ gtt (drops)/min}$$

  Find milliliters per hour by dividing 1,000 mL by 10 hours:

$$\text{gtt (drops)/min} = \frac{\text{volume (mL)} \times \text{drop factor (gtt (drops)/mL)}}{\text{time (in minutes)}}$$

$$\text{gtt (drops)/min} = \frac{1{,}000 \text{ mL} \times 60}{600 \text{ (60 min} \times 10 \text{ h)}}$$

$$= \frac{60{,}000}{600}$$

$$= 100 \text{ gtt (drops)/min}$$

Administration may be achieved by gravity infusion, which requires the nurse to calculate the infusion rate in drops per minute. If using a gravity or free-flowing IV, calculate the drip rate required to achieve the desired infusion rate. A method for determining flow rate is described in the accompanying Guidelines for Nursing Care 41-2. This method requires the nurse to know the amount of solution to be delivered, the total infusion time (in minutes), and the drop factor for the infusion tubing in use. The drop factor, or drops per milliliter of solution, is determined by the size of the opening in the infusion apparatus. It varies among different products from different companies. Most health facilities use the products of a single company. The most common drop factors are macrodrop systems (10, 15, 20 drops/mL), a microdrip (60 drops/mL), and a blood administration set (10 drops/mL). Microdrip is used most often when small fluid volumes are administered, such as a rate less than 75 mL/hr. Macrodrop tubing is commonly used for rates greater than 75 mL/hr.

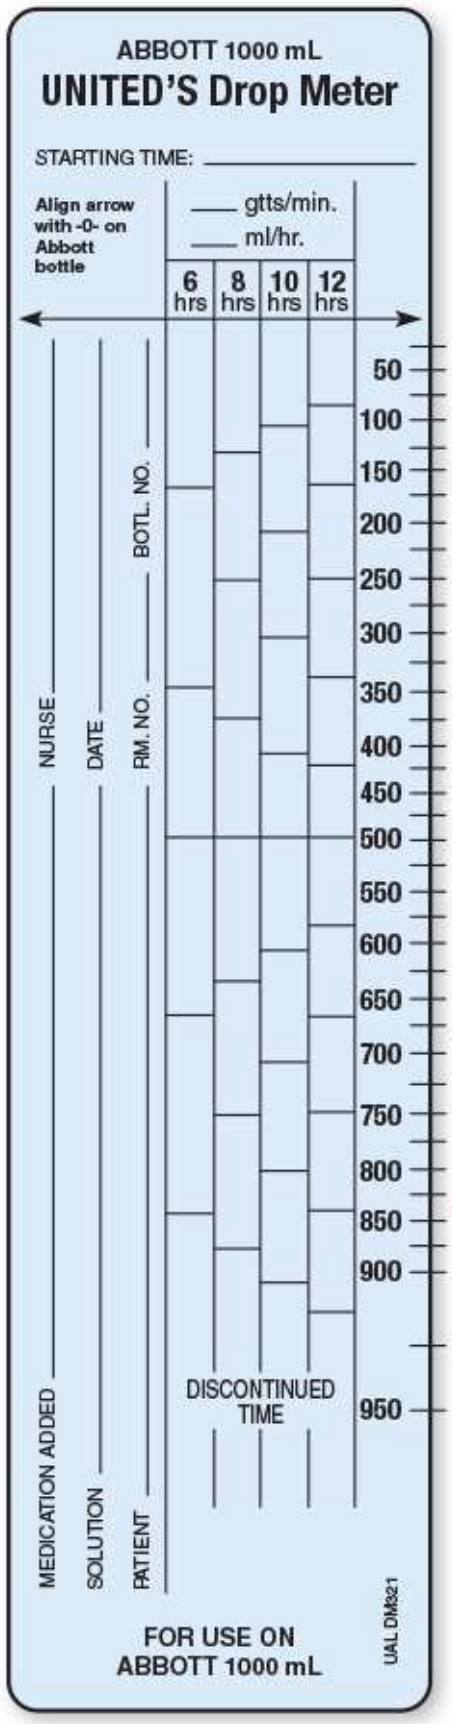

FIGURE 41-18. Sample time tape for an IV solution container.

Place a time tape (Fig. 41-18) on the container of solution to provide a quick reference for the nurse to monitor the rate at which the solution is entering the patient. The tape gives an hourly indication of where the fluid level should be at a given time.

Consider **Jack Soo Park**, the patient who received too much IV fluid. When planning Mr. Park's care, the nurse would need to include frequent assessments of the IV infusion to ensure that it is infusing at the proper flow rate. Ensuring the use of an infusion pump significantly reduces the potential for an infusion error.

A less commonly used volume-control device may be used to reduce the risk for fluid overload or medication overdose. These devices may be used in pediatric settings in which catastrophic fluid overload is possible if adult fluid

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

doses are inadvertently administered. A volume-control device may also be used to deliver intermittent medications that need to be further diluted and given over a specified time. Many facilities have reduced or eliminated the use of volume-control devices as a result of advances in infusion pump technology (Kyle & Carman, 2021). Concerns related to use of these devices include the lack of identification of the drug placed in the device and the potential for chemical inactivation or precipitation that may occur in the device or IV tubing when multiple medications are administered using the same set (Kyle & Carman, 2021).

SOLUTION AND TUBING CHANGES

If more than one container of solution is prescribed for the patient, attach additional containers using the method determined by the facility. The frequency of administration set tubing changes varies. The Infusion Nurses Society (Gorski et al., 2021) provides guidelines related to administration set change and recommends routine changes of administration sets (tubing) based on the type of solution administered via the tubing and frequency of the infusion (continuous vs. intermittent). In addition, infusion administration sets should be changed immediately upon suspected contamination or when the integrity of the administration product or system has been compromised (Gorski et al., 2021, p. S123). Infusion administration sets should also be changed a new VAD is placed (Gorski et al., 2021, p. S124). Table 41-8 (on page 1704) outlines additional recommended infusion administration set changes based on the type of infusion and device, according to INS Standards. It is important to be familiar with the particular policies and procedures of a given facility as well.

COMPLICATIONS OF IV THERAPY

Nurses must maintain current knowledge related to prevention, assessment, recognition, and management of vascular access device-related complications (Gorski et al., 2021; Willis, 2020). Regularly assess venous access sites to detect common complications of IV therapy including infiltration (inadvertent leakage of nonvesicant [agent capable of causing tissue damage] IV solution into surrounding tissue), extravasation (inadvertent leakage of vesicant IV solution into surrounding tissue), phlebitis (inflammation of the wall of a vein), thrombophlebitis (blood clot in a vein, causing inflammation), and infection. Venous access device-related infections are a potentially serious complication related to IV therapy. The development of venous access device–related infection can range from the minor irritation of a localized site infection to a potentially life-threatening bloodstream infection or septicemia (Berndt & Steinheiser, 2019; Casimero et al., 2020).

Table 41-8 Recommended Administration Set Change Schedule

TYPE OF INFUSION/TYPE OF DEVICE	RECOMMENDED FREQUENCY
• Primary and secondary continuous administration sets used to administer fluids other than lipid, blood, or blood products	• Change no more frequently than every 96 hours. • Change at least every 7 days. • Change if VAD is changed • Change if the integrity of the product or system has been compromised • If the first unit of blood requires 4 hours for transfusion, do not reuse toe administration set or filter. Most standard filters have a 4-unit maximum capacity for reuse.
• Intermittent administration sets	• Every 24 hours
• Administration sets with inline or add-on filters used to administer PN	• Change every 24 hours or with each new PN container.
• Administration sets used to administer IV lipid emulsions (ILE)	• Change every 12 hours and/or with each new ILE container.
• Administration sets used to administer blood and blood components	• If the first unit of blood requires 4 hours for transfusion, do not reuse administration set or filter. Most standard filters have a 4-unit maximum capacity for reuse.

(2021). Infusion therapy. Standards of practice. (8th ed.). *Journal of Infusion Nursing*, *44*(Suppl 1), S1–S224. https://doi.org/10.1097/NAN.0000000000000396

Technology Alert

Compliance with evidence-based central venous catheter care bundles to reduce the rate of catheter-associated bloodstream infection can be increased with the use of an electronic dashboard to monitor CABSI bundle-adherence and provide feedback related to compliance (Chemparathy et al., 2021).

Local complications, such as infiltration, phlebitis, and thrombophlebitis, occur more frequently than do systemic complications. However, systemic complications (e.g., fluid overload, embolus, sepsis) are more serious and may be life threatening. Central venous catheters are available that are impregnated with antiseptics and coated with antibiotics (antiinfective CVADs); use of these devices should be considered for patients at high risk for acquiring a catheter-related infection, such as expected dwell time of more than 5 days or those with enhanced risk of infection, including neutropenic, transplant, burn, or critically ill patients (Gorski et al., 2021). Consult facility policy for guidance concerning catheter site care as well as the manufacturer's recommendations and precautions. An additional recommendation to prevent intravascular catheter-related infections is the use of a 2% chlorhexidine wash for daily skin cleansing for patients in the intensive care unit with a CVAD, if other catheter-associated bloodstream infection (CABSI) prevention strategies have not been effective (Gorski et al., 2021; O'Grady et al., 2017). Table 41-9 outlines potential complications of IV infusions, noting common causes, signs and symptoms, and pertinent nursing considerations.

The patient can be an important source of information regarding the possibility of complications associated with IV therapy. If the patient is uncomfortable, check that the infusion is entering the vein as intended, the flow rate is not too rapid, the patient's position is satisfactory, and the circulatory status of the patient is intact. Anxiety about receiving an infusion can also cause discomfort for the patient. Provide appropriate and accurate information to the patient regarding the infusion to help decrease anxiety.

Assess for any deviation from the normal skin temperature of the site. For example, cool skin can indicate infiltration while warm skin can indicate phlebitis or infection. Also note the tone of the skin at the venous access site in comparison to the surrounding skin. Pale or blanched skin can be a sign of infiltration, whereas red/purple/darker skin can indicate inflammation related to phlebitis or infection. Pus at the IV site indicates infection, while leaking fluid at the site indicates infiltration. Finally, fully investigate discomfort, pain, swelling or edema at the site as these symptoms are associated with all of the five major complications listed earlier. Encourage patients to report any changes in the catheter site or any new discomfort (O'Grady et al., 2017). Use a standardized scale for assessing and documenting phlebitis (Gorski et al., 2021). Box 41-1 (on page 1706) identifies one scale that can be used to assess and document phlebitis.

VENOUS ACCESS CARE AND MANAGEMENT

Site Care

Scrupulous care of the infusion site is necessary to help control contamination and to help prevent the introduction of microorganisms into the bloodstream. Site care and dressing changes are performed using aseptic non touch technique (ANTT®) (Gorski et al., 2021); in the nontouch technique, the practitioner touches a site or equipment only as absolutely necessary, even when wearing sterile gloves (ANTT® , 2021). Appropriate skin antisepsis, maintenance of an intact and patent dressing at the insertion site, use of appropriate dressing change regimens, appropriate administration tubing replacements (previously discussed), and appropriate IV needleless connector disinfection are important means of preventing infection. Use of >0.5% chlorhexidine in alcohol solution is preferred for skin antisepsis (Gorski et al., 2021; Sarani et al., 2018). If there is a contraindication to alcoholic chlorhexidine solution, tincture of iodine, an iodophor (povidone-iodine), or 70% alcohol may instead be used (Gorski et al., 2021; Mimoz et al., 2015; O'Grady et al., 2017). Use chlorhexidine with caution in infants up to age 14 days, premature infants, and low-birth-weight infants due to the risk of skin irritation and chemical burns (Gorski et al., 2021). The use of topical antimicrobial ointment to VAD insertion sites (except hemodialysis catheter sites) as part of routine site care is not recommended because of their potential to promote fungal infections and antimicrobial resistance (Gorski et al., 2021; O'Grady et al., 2017).

Table 41-9 Complications Associated With Intravenous Infusions

COMPLICATION/CAUSE	SIGNS AND SYMPTOMS	NURSING CONSIDERATIONS
Infiltration: the escape of fluid into the subcutaneous tissue Dislodged needle Penetrated vessel wall	Swelling, pallor, coldness, or pain around the infusion site; significant decrease in the flow rate	Check the infusion site every hour for signs/symptoms. Discontinue the infusion if symptoms occur. Restart the infusion at a different site.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

		Use site-stabilization device.
Venous access device–related infection: Improper hand decontamination/hand hygiene Frequent disconnection of tubing, access ports, and/or access caps Poor insertion technique, multiple insertion attempts Multilumen catheters Long-term catheter insertion Frequent dressing changes Inadequate/improper decontamination of hub prior to use An IV solution that becomes contaminated when solutions are changed, a medication is added, or the solution is allowed to infuse for too long a period Inappropriate administration set changes	Erythema, edema, induration, drainage at the insertion site Fever, malaise, chills, other vital sign changes	Perform hand hygiene before and after palpating catheter insertion sites; before and after inserting, replacing, accessing, and dressing a venous access device. Assess catheter site routinely. Notify health care team immediately if any signs of infection. Use scrupulous aseptic technique when starting an infusion. Follow best-practice guidelines for site care, changing of administration tubing sets, connectors, caps and other administration equipment. Follow facility protocol for culture of drainage. Consider use of 2% chlorhexidine wash for daily skin cleansing.
Phlebitis: an inflammation of a vein Mechanical trauma from needle or catheter Chemical trauma from solution	Local, acute tenderness; redness, warmth, and slight edema of the vein above the insertion site	Use a phlebitis scale to assess and document phlebitis. Discontinue the infusion immediately. Apply warm compresses to the affected site. Avoid further use of the vein. Restart the infusion in another vein.
Thrombus: a blood clot Tissue trauma from needle or catheter	Symptoms similar to phlebitis IV fluid flow may cease if clot obstructs needle.	Stop the infusion immediately. Apply warm compresses as prescribed or according to facility policy. Restart the IV at another site. *Do not rub or massage the affected area.*
Speed shock: the body's reaction to a substance that is injected into the circulatory system too rapidly Too rapid a rate of fluid infusion into circulation	Pounding headache, fainting, rapid pulse rate, apprehension, chills, back pains, and dyspnea	Use the proper IV tubing. Carefully monitor the rate of fluid flow. Check the rate frequently for accuracy. A time tape is useful for this purpose.
Fluid overload: the condition caused when too large a volume of fluid infuses into the circulatory system Too large a volume of fluid infused into circulation	Engorged neck veins, increased blood pressure, and difficulty in breathing (dyspnea)	If symptoms develop, slow the rate of infusion. Notify the health care team immediately. Monitor vital signs. Carefully monitor the rate of fluid flow. Check the rate frequently for accuracy.
Air embolus: air in the circulatory system Break in the IV system above the heart level, allowing air in the circulatory system as a bolus	Respiratory distress Increased heart rate Cyanosis Decreased blood pressure Change in level of	Pinch off catheter or secure system to prevent entry of air. Place patient on left side in Trendelenburg position. Call for immediate assistance.

	consciousness	Monitor vital signs and pulse oximetry.

Box 41-1 Phlebitis Scale

Grade and document phlebitis according to the most severe presenting indicator.

Grade	Clinical Criteria
0	No symptoms
1	Erythema at access site with or without pain
2	Pain at access site with erythema and/or edema
3	Pain at access site with erythema and/or edema Streak formation Palpable venous cord
4	Pain at access site with erythema and/or edema Streak formation Palpable venous cord >1 inch in length Purulent drainage

Source: Gorski, L. A., Hadaway, L., Hagle, M. E., Broadhurst, D., Clare, S., Kleidon, T., Meyer, B. M., Nickel, B., Rowley, S., Sharpe, E., Alexander, M., & Infusion Nurses Society. (2021). Infusion therapy. Standards of practice. (8th ed.).*Journal of Infusion Nursing*, *44*(Suppl 1), S139. https://doi.org/10.1097/NAN.0000000000000396

Transparent semipermeable membrane (TSM) dressings are commonly used to protect the insertion site. TSM dressings (e.g., Tegaderm™ or OpSite IV™) allow easy inspection of the VAD site and permit evaporation of moisture that accumulates under the dressing. Sterile gauze may also be used to cover the catheter site. A gauze dressing is recommended if the patient is diaphoretic, the site is bleeding or oozing, or there is drainage from the exit site; replace it with a TSM once this is resolved (Gorski, 2020; O'Grady et al., 2017). Chlorhexidine-impregnated dressings are recommended for use as VAD site dressings for certain patient populations, including oncology patients with implanted ports, adult patients with short-term nontunneled CVADs, and patients with an epidural access device (Gorski et al., 2021).

Facility policy generally determines the type of dressing and the intervals for dressing change. Perform site care and replace TSM dressings at least every 7 days (except neonatal patients) or immediately if the dressing becomes damp, loosened, visibly soiled or has a lifted/detached border; blood or drainage is present; or there is compromised skin integrity under the dressing (Gorski et al., 2021). Change sterile gauze dressings at least every 2 days, or if the integrity of the dressing is disrupted (damp, loosened, visibly soiled) (Gorski et al., 2021). Consider the use of sterile adhesive removers and skin barrier film to prevent medical adhesive–related skin injury (MARSI) (Fumarola et al., 2020; Gorski et al., 2021; Zhao et al., 2018). Do not submerge venous catheters and catheter sites in water; showering is permitted with use of impermeable coverings (clear plastic wrap or a device designed for this purpose) to protect the catheter and connections (Gorski et al., 2021; O'Grady et al., 2017). Skill 41-2 (on pp. 1725–1727) reviews how to monitor an IV site.

Entry-Point Disinfection

Venous access device administration set entry points, end caps, and needleless connectors must be vigorously scrubbed and disinfected prior to each access to reduce the risk for introduction of microorganisms and prevent venous access device–related infection (Gorski et al., 2021). Acceptable disinfecting agents include 70% isopropyl alcohol, iodophors, or chlorhexidine in alcohol solution (Berndt & Steinheiser, 2019; Gorski et al., 2021). Friction is needed to physically remove microorganisms from the top, sides, and threads of the access cap. The length of time for the mechanical scrub varies based on the specific device and cleansing agent; recommended time frames include 5 to 15 seconds (Gorski et al., 2021). Allow the antiseptic to dry completely (5 seconds when using alcohol; 20 seconds when using chlorhexidine with alcohol; more than 6 minutes when using povidone iodine) (Gorski et al., 2021).

Passive Disinfection Caps

The use of passive disinfection caps (port protectors) is an effective means to reduce infection associated with central and peripheral VADs (Barton, 2019a; Gorski et al., 2021; Stango et al., 2014). A passive disinfection cap is attached to the venous access end cap, needleless connector, and/or each access site on IV administration set tubing and is left in place between device accesses (Casimero et al., 2020). These caps contain an antiseptic-impregnated sponge that dispenses the antiseptic over the connector's top and threads and protects the hub from contamination by acting as a

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

physical barrier to touch or airborne sources (Barton, 2019a; Casimero et al., 2020). Passive disinfection caps are discarded after removal from the venous access device and should never be reattached (Gorski et al., 2021). Figure 41-19 provides an example of a passive disinfection cap in place on a needleless connector.

FIGURE 41-19. Disinfection cap in place on a needleless connector. (Courtesy of 3M © 3M 2015. All rights reserved.)

If multiple accesses of the venous access device are required, such as with medication administration (i.e., several flush syringes and administration sets), additional disinfection of the end cap or needleless connector is required before each entry (Gorski et al., 2021). Refer to facility policy for scrub time, technique, and agents.

Needleless Connectors

Needleless connectors should be changed no more frequently than every 96 hours (Gorski et al., 2021). When a needleless connector is used as part of a continuous IV infusion, the connector is changed when the primary administration set is changed. A recommended administration set change schedule is detailed in Table 41-8 on page 1704. Needleless connectors should also be changed if the connector is removed for any reason, it there is residual blood or debris within the connector, prior to drawing a sample for blood culture from the venous access device, upon contamination of the connector, based on the manufacturer's recommendations, and per facility policy and/or procedures (Gorski et al., 2021, p. S106).

It is important to follow the manufacturers' directions for use when flushing, clamping, and disconnecting syringes and IV administration tubing or any other device from needleless connectors. In the absence of the manufacturer's directions, identify the internal mechanism for fluid displacement reported by the manufacturer for the type of needleless connector being used and use the appropriate sequence for flushing, clamping, and disconnecting based on the type of needleless connector to prevent connection/disconnection reflux (Gorski et al, 2021).

Multiple Continuous Infusions

It is important to differentiate and label individual fluid infusions in patients with multiple, continuously infused IV fluids (Gorski et al., 2021). The Infusion Nurses Society recommends tracing all catheters/administration sets/add-on devices between the patient and solution container before connecting or reconnecting any infusion/ device, at each care transition to a new setting or service, and as part of the handoff process (Gorski et al., 2021, p. S123). Some facilities have responded to this challenge by implementing color-coded labeling systems to organize multiple fluids in a visually safe manner and improve accuracy and patient safety (Cho et al., 2013). Commercial devices are also available to organize and label IV tubing and other tubing, cables, wires, and cords that may be present at the bedside in acute care as well as in the patient's home setting. These devices also help keep tubing from dropping to the ground and potential tangles, damage, or contamination (Haynes et al., 2015).

Venous Catheter Securement/Stabilization Devices

Stabilization and securement products are designed to control movement at the catheter hub, decreasing catheter movement internally and externally (Hill & Moureau, 2019, as cited in Barton, 2020, p. S28). Manufactured venous catheter securement/stabilization systems are commercially available. These systems are recommended for use on all venous access sites, particularly central venous access sites, to preserve the integrity of the access device, minimize catheter movement at the hub, and to prevent catheter migration and loss of access (Barton, 2020; Gorski et al., 2021; O'Grady et al., 2017). Many of these devices also function as an integrated dressing product. The use of a stabilization device can also decrease the risk of infiltration, phlebitis, skin damage, occlusion, leaking, catheter-related infection, and unscheduled restart rates/loss of the catheter (Marsh et al., 2015; Smith & Hannum, 2008). There are many devices available, including plastic shields and adhesive anchors. Some securement devices are intended for use with a specific venous access device, such as a subcutaneous anchor for use with PICCs (Rowe et al., 2020).

FIGURE 41-20. IV shield in place on the hand.

Hard plastic shields (Fig. 41-20) that are ventilated and secured with tape are often used in pediatric settings. In addition, they are helpful in minimizing venous access complications with geriatric patients (Smith & Hannum, 2008). Adhesive anchors eliminate the need for tape but are costlier and involve the use of strong adhesives that might make it difficult to change the dressing without dislodging the catheter. A skin barrier should be applied to the skin exposed to the adhesive to reduce the risk of medical adhesive–related skin injury (Gorski et al., 2021).

The integrity of the stabilization device should be assessed with each dressing change, and the device itself should be changed according to the manufacturer's directions (Gorski et al., 2021). A dislodged vascular access device should never be readvanced into the vein; a dislodged device should be removed, reinserted at a new site, or exchanged (Gorski et al., 2021).

CAPPING A PRIMARY LINE FOR INTERMITTENT USE

When a continuous IV is no longer necessary, the primary IV line (PIVC or CVAD) can be capped and converted to an intermittent infusion device. A capped line consists of the IV catheter connected to a short length of extension tubing sealed with a cap. Capping of a VAD provides venous access for intermittent infusions or emergency medications. VADs used for intermittent infusions should be flushed with preservative-free 0.9% sodium chloride solution and aspirated for a blood return prior to each infusion to assess catheter function (Gorski et al., 2021). Flushing of the device is also required after each infusion to clear the infused medication or other solution from the catheter lumen. Vascular access devices are locked after completion of the flush solution at each use to decrease the risk of occlusion (Gorski et al., 2021). According to the guidelines from the INS, PIVCs are locked with preservative-free 0.9% sodium chloride; CVADs should be locked with either a heparin solution (10 units/mL) or preservative-free 0.9% sodium chloride after each intermittent use, according to the directions for use for the specific CVAD and needleless connector (Gorski et al., 2021). If the device is not in use, periodic flushing according to facility policy is required to keep the catheter patent. Antimicrobial locking solutions are sometimes used in specific situations, such as with patients with long-term CVADs or in high-risk patient populations (Gorski et al., 2021). The accompanying PICOT in Practice box highlights an example of evidence-based decision making regarding flushing of CVADs in infants and children.

PICOT in Practice

ASKING CLINICAL QUESTIONS: CENTRAL VENOUS CATHETERS IN INFANTS AND CHILDREN

Scenario: You are a staff nurse who works on a pediatric medical/surgical unit. You receive report on a patient who was admitted with vomiting 4 days ago. The patient is receiving intermittent flushes to prevent occlusion of a long-term central venous catheter. The patient has a prescription for normal saline (0.9% sodium chloride) flushes. You have seen heparin prescribed for patients with long-term central venous catheters in the past and wonder if there is a difference.

You decide to search the literature for best practice.

- **Population:** Pediatric patients with long-term central venous catheters
- **Intervention:**Normal saline (0.9% sodium chloride) versus heparin flushes
- **Comparison:**Low-molecular-weight heparin injections
- **Outcome:**Occlusions of central venous catheters
- **Time:** Duration of hospitalization.

PICOT Question: Among pediatric patients with long-term central venous catheters, does normal saline (0.9%

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

sodium chloride) when compared to heparin flushes and to low-molecular-weight heparin injections prevent occlusions during the hospitalized stay?

Findings:

1. Bradford, N. K., Edwards, R. M., & Chan, R. J. (2020). Normal saline (0.9% sodium chloride) versus heparin intermittent flushing for the prevention of occlusion in longterm central venous catheters in infants and children. *Cochrane Database of Systematic Reviews, 4*(4), CD010996. https://doi.org/10.1002/14651858.CD010996.pub3

2. Pelland-Marcotte, M.-C., Amiri, N., Avila, M. L., & Brandão, L. R. (2020). Low molecular weight heparin for prevention of central venous catheterrelated thrombosis in children. *Cochrane Database of Systematic Reviews*, *6*(6), CD005982. https://doi.org/10.1002/14651858.CD005982.pub3.

Four studies with a total of 255 participants were all undertaken in large teaching (tertiary) hospitals and directly compared the use of saline and heparin. The review found that there was not enough evidence to determine the effects of intermittent flushing with normal saline versus heparin to prevent occlusion in longterm central venous catheters in infants and children. It remains unclear whether heparin is necessary to prevent occlusion. Evidence was also insufficient to confirm on the outcomes catheter occlusion, days of catheter patency, episodes of catheter-related bloodstream infection, and other side effects of low-molecular-weight heparin.

Strength of Evidence: Level I systematic review

Recommendations: You write an abstract and submit it to the evidence-based practice committee to discuss your findings. You cite the strength of the evidence in the Cochrane reviews and highlight that there is no difference in intermittent flushing with normal saline versus heparin to prevent occlusion in longterm central. In your proposal, you compare the cost of normal saline versus heparin. The use of heparin incurs costs to health systems with no advantages over normal saline flushes according to the evidence. There is also greater risk with the administration of heparin.

DISCONTINUATION OF THE INFUSION

Remove the PIVC when the PIVC is no longer required as part of the plan of care; has not been used for 24 hours or more; or when site assessment and/or clinical signs and symptoms of systemic complications are present (Gorski et al., 2021). Do not remove based solely on length of dwell time (Gorski et al., 2021). After performing hand hygiene, put on gloves, clamp the IV tubing, and remove the tape and sterile dressing. Avoid bending the catheter while it is withdrawn to prevent breakage. Apply pressure immediately to the area just above the insertion site until hemostasis is achieved. Apply pressure using a dry, sterile gauze pad rather than using an alcohol preparation; alcohol tends to burn and does not stop blood flow from the puncture wound. Apply an occlusive dressing to the site. Document the date and time of removal, the name of the person removing the device, and the assessment of the site.

Nurses or specialized IV team nurses may be responsible for removing a midline or PICC line. Other CVADs are usually removed by advanced practice professionals. Specific protocols must be followed to prevent breakage or fracture of the catheter.

HOME INFUSION

Home infusion therapy allows patients to be discharged earlier from acute care and/or avoid hospitalization and return to their home or other community-based care setting (Gorski, 2020). Portable infusion pumps and the support of community-based care nurses have made this a part of the plan of care for many patients. After a patient has been identified as a candidate for home infusion therapy, begin assessment and education to ensure a successful outcome. Candidates for infusion pump IV therapy in the home should meet certain criteria. They should be medically stable; have support from a motivated, capable, and willing caregiver; have access to a telephone; and have access to electricity and refrigeration (Fields et al., 2020). Patients can receive pain medication, antimicrobials, chemotherapy, parenteral nutrition, or other medications through portable infusion pumps at home.

Teaching Tips 41-1

IV THERAPY

Health Topic	Teaching Tip	Why Is This Important?
Aseptic technique	• Proper handwashing technique • Dressing changes and care of site/device • Proper technique for infusing medications	Prevent local and systemic infection
Equipment use	• Proper technique for using all equipment and flushing of CVAD	Prevent medication/infusion therapy error and complications such as

	• Safe storage, maintenance, and disposal of solutions, supplies, and equipment • Protection of device/insertion site when showering or bathing	bleeding, embolus, and/or infection related to improper use of equipment and flushing of CVAD.
Assessment Skills	Assessing for any indications of an infection or other complications and how to report such problems	Understanding of signs of infection and other complications promotes early detection and intervention.
Supplies	Obtaining supplies to continue home infusions	Continued supplies are needed to maintain prescribed home therapy.
Resources	How and why to contact health care team if questions or problems arise Use of educational resources on the Internet that are reputable, usable, and accessible	Understanding of available resources and when it is appropriate to use these resources promotes engagement and maintenance of prescribed therapy. Ensure use of appropriate education sources that incorporate best-practice, support patient safety, and reduce risk of misinformation

Source: Adapted from Gorski, L. A., Hadaway, L., Hagle, M. E., Broadhurst, D., Clare, S., Kleidon, T., Meyer, B. M., Nickel, B., Rowley, S., Sharpe, E., Alexander, M., & Infusion Nurses Society. (2021). Infusion therapy. Standards of practice. (8th ed.). *Journal of Infusion Nursing*, *44*(Suppl 1), S1–S224. https://doi.org/10.1097/NAN.0000000000000396

PICCs and other CVADs are the most common type of catheter used for home health care patients. Home health care nurses play a crucial role in supporting patients and families/caregivers concerning successful management of VADs, IV infusions, and observing for potential complications. The patient and any caregivers should understand the role of the caregiver in giving infusions; monitoring the patient's condition; and managing required medications, equipment, and supplies as well as be able to perform the related skills (Fields et al., 2020). See Teaching Tips 41-1.

Administering Blood and Blood Products

A blood transfusion is the infusion of whole blood or a blood component such as plasma, red blood cells, cryoprecipitate, or platelets into the patient's venous circulation. Red blood cells have the important role of carrying oxygen from the lungs to all body tissues. Oxygen is essential to maintain normal cellular metabolism and cellular integrity. Platelets and the coagulation factors found in cryoprecipitate and plasma are essential for establishing homeostasis following an injury or invasive procedure. These blood components promote normal blood clotting, thus are important in the prevention of excessive blood loss. A blood product transfusion is given when a patient's red blood cells, platelets, or coagulation factors decrease to levels that compromise a patient's health. Blood transfusions are not without risk, however. Potentially life-threatening complications include allergic reaction and anaphylactic reaction, hemolytic reaction, transfusion-related acute lung injury, circulatory volume overload, immunosuppression, and transmission of infectious diseases are a risk associated with blood product transfusion (Carman et al., 2018). It is important that the potential benefits of the transfusion be considered against the potential risks (American Red Cross, 2021; Carman et al., 2018). Blood is a vital but limited resource, and clinical judgment and use of current guidelines and recommendations are crucial in determining whether the associated risks outweigh the patient's need (American Red Cross, 2021; Carman et al, 2018). The person receiving the blood is the recipient. The person giving the blood is the donor.

BLOOD TYPING AND CROSS-MATCHING

Before a blood product can be given to a patient, it must be determined that the blood of the donor is compatible with that of the patient. If incompatible, clumping and hemolysis of the recipient's blood cells result, and death can occur. The laboratory examination to determine a person's blood type is called **blood typing**. The process of determining compatibility between blood specimens is **cross-matching**.

Blood Types

Blood type, an inherited trait, is determined by the type of antigens and antibodies present in the blood. An **antigen** is a substance that causes the formation of antibodies. An **antibody** is a protein substance developed in the body in response to the presence of an antigen that has entered the body. An agglutinin is an antibody that causes a clumping of specific antigens. The four main blood types or groups in the ABO system of blood typing are A, B, AB, and O.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Some groups are further broken down into subgroups. People who have type A blood have an A antigen on their red blood cells, those with type B blood have B antigens on their cells, those in the AB group have both A and B antigens, and people with type O blood have neither A nor B antigens on their red blood cells. People in each blood group have the agglutinins to the red blood cell antigens that they lack. Group A people have the agglutinin for B; group AB people have no agglutinins for A and B, whereas group O people have both A and B agglutinins in their blood serum. If a person with type O blood is transfused with blood from a person with either group A or group B blood, there would be destruction of the recipient's red blood cells because the recipient's anti-A or anti-B agglutinins would react with the A or B antigens in the donor's red blood cells. This explains why people with type AB blood are often called universal recipients (because people in this blood group have no agglutinins for either A or B antigens), and group O people are often called universal donors (because they have neither A nor B antigens).

Rh Factor

The Rh factor is an inherited antigen in human blood. There are five antigens in the Rh system, but the one designated D is of first concern. A person whose blood contains a D antigen is called Rh positive; an Rh-negative person lacks this D antigen. An Rh-negative person must receive blood from another Rh-negative person. If Rh-positive blood is administered to an Rh-negative person, the recipient develops anti-Rh agglutinins. Subsequent transfusion with Rh-positive blood may cause serious reactions with clumping and hemolysis of red blood cells.

BLOOD DONORS

Blood donors must be selected with care. Not only must the donor's blood be typed accurately, but it is also important to determine that the donor is free of infectious disease. Transfusion-transmitted infections are infections resulting from the introduction of a pathogen into a person through blood transfusion (CDC, 2020). Transfusion-transmitted infections occur from the transfer of bacteria, viruses, prions, and parasites (CDC, 2020). Donor screening using questionnaires and laboratory tests helps reduce the risk of an infectious organism being transmitted by blood transfusion (CDC). The blood will be tested for Chagas disease, human immunodeficiency virus (HIV), hepatitis B and C virus (HBV and HBC), human T-lymphotropic virus (HTLV), syphilis, West Nile virus, Zika virus, Babesia, cytomegalovirus (CMV), and bacterial contamination (CDC, 2020).

The donor is examined carefully at the time of donation and receives specific information about eligibility and a confidential method to allow or disallow the distribution of the donated blood. Prospective donors must meet minimum requirements for age, height, and weight (American Red Cross, n.d.a). Prospective donors are questioned about their lifestyle and health history, including questions about diseases, health conditions, past surgeries, tattoos, body piercing, travel, sexual habits, and medication/drug use (American Red Cross, n.d.c). People may give blood only if their blood count (hemoglobin or hematocrit), temperature, pulse, and blood pressure are within normal ranges.

Some patients who know in advance that they will need blood can donate their own blood for transfusion, known as **autologous transfusion** or autotransfusion. Autologous transfusion eliminates the danger of transmitting cross-infection from donor to recipient and decreases the risk for complications from mismatched blood. However, this technique requires advance planning; blood can be donated every 4 to 7 days and up to 3 business days before surgery is planned, as long as the patient meets donation guidelines (American Red Cross, n.d.d). Autologous donation is not complication free; administration errors and infection are still possible even with autologous transfusion.

An additional transfusion technique related to autologous transfusion is utilized frequently in surgical settings. It is called intraoperative blood salvage. With this technique, a patient's own blood can be collected from specialized suction canisters, tubes and drains to allow for autologous transfusions.

BLOOD COMPONENTS

Whole blood is rarely used unless blood loss has been massive. This is because whole blood can be easily separated into its components. This allows patients to receive only the blood product they need, decreasing the risk for fluid overload and promoting blood product availability to more patients. Guidelines exist to balance the benefit of treating the patient with the desire to avoid unnecessary transfusion, with associated costs and potential harm (American Red Cross, 2021; Gorski et al., 2021). For example, a patient may need red blood cells but not the blood plasma and its constituents. Red blood cells can therefore be administered in concentrated form, called packed red blood cells (PRBCs). The decision to transfuse is based on laboratory test results and individual patient characteristics, clinical condition, and symptoms.

In situations in which there is a deficit in plasma proteins and/or components of the blood important for normal functioning of coagulation and fibrinolysis (including complement), administration of plasma may be a more appropriate option. Fresh-frozen plasma (FFP) is particularly useful in emergencies that involve massive blood loss because it will restore both coagulation factors and blood volume. It is also an excellent protein containing blood volume expander when a patient develops a sudden critical fluid deficit: for example, in a patient who is severely burned and losing plasma rapidly from burn areas. Separate components of plasma that are also used therapeutically include human albumin (used for hypovolemic shock, albuminemia, liver failure), cryoprecipitate (used to treat bleeding due to hemophilia, disseminated intravascular coagulation, or depletion of coagulation factors such as

fibrinogen following massive blood loss), and gamma globulins, the antibody-containing part of plasma (used for immunoglobulin deficiencies).

Platelet infusion is indicated for the treatment or prevention of bleeding associated with deficiencies in the number or quality of a patient's platelets. The demand for platelets has risen noticeably during the past several decades; specialized products and preparation methods have been developed to reduce the risk for complications and improve the patient's response to platelet therapy.

Health care organizations are encouraged to create a patient blood management (PBM) program to optimize the care of patients who might require a blood transfusion (Gorski et al., 2021). These multidisciplinary committees establish, monitor, promote and enforce patient blood management activities (PBM) (American Red Cross, 2021) and assist clinicians to make decisions about appropriate use of transfusion and elimination of unnecessary transfusions (Gorski et al., 2021). Representation by nurses on these types of committees provides the opportunity to advocate for evidence-based changes in practice and wise stewardship of resources (American Red Cross, 2021).

INITIATION AND TRANSFUSION OF BLOOD

Identification of patients at risk for complications and patient monitoring during and after transfusion of blood products is essential because of ongoing risk for transfusion reaction (Carman et al., 2018; DeLisle, 2018). The nurse should always follow facility blood product transfusion policies and protocols. Two adults in the presence of the patient should perform pretransfusion safety checks together prior to blood product administration. In the hospital or outpatient setting, this should be two practitioners trained in the identification of the recipient and blood components, such as registered nurses, advanced practice nurses, or physicians (Gorski et al., 2021). In home settings, it should be the registered nurse and a responsible adult (Gorski et al., 2021). Verify the prescribed transfusion intervention and verify that informed consent was obtained by the prescriber (DeLisle, 2018). Educate the patient about the signs and symptoms of a reaction and the importance of reporting so they will be aware if one develops and take action (DeLisle, 2018; Gorski et al, 2021). Verify the patient's identity by at least two independent identifiers, such as the patient's full name and birthdate. In an in-patient or long-term care setting, the nurse confirms that this information matches the information on the patient's identification band. The patient's blood type and Rh factor should be checked against the blood type and Rh factor of the transfusion product. In addition, the nurse should always confirm the donation identification number (a code to track the blood back to its donor) and the expiration date and date/time of issue of the blood product. Bar codes on blood products provide an additional safety measure to identify, track, and assign data to transfusions. In addition, the facility that prepared the blood must be identified. While such systems offer the potential for improved safety, the nurse must always recognize that there is no replacement for vigilant and consistent safety checks.

The procedure for administering a blood transfusion is similar to the procedure for starting an IV infusion of fluids, with a few differences. Blood or blood components may be transfused via a 20- to 24-gauge PIVC for an adult. When rapid transfusion is required, a larger-sized catheter gauge is recommended (18 to 20 gauge) (Gorski et al., 2021). CVADs may also be used to administer a transfusion (Gorski et al., 2021). Transfusion for infants and children is usually given using a 22- to 24-gauge catheter (umbilical vein in neonates or a peripheral vein large enough to accommodate the catheter) (Gorski et al., 2021).

The Infusion Nurses Society Standards of Practice identifies important components of safe blood transfusion and include (Gorski et al., 2021):

- Baseline assessment prior to obtaining blood for transfusion including measurement of vital signs, lung assessment, identification of conditions that may increase the risk of transfusion-related adverse reactions (e.g., fever, heart failure, renal disease), the presence of an appropriate and patent VAD and current laboratory values.
- Use an in-line filter or an add-on filter that is designated for the specific blood or blood component and for the administration set in use; refer to the manufacturer's guidelines and facility policies.
- Plan to administer the blood or blood component within 4 hours; refer to facility guidelines for infusion times for specific blood components.
- Use an electronic infusion pump labeled for blood transfusion.
- Administer blood or blood component infusions with 0.9% sodium chloride; do not add or infuse any other solutions or medications through the administration set and do not infuse transfusions through other administration sets.
- Start nonemergent transfusions slowly and carefully monitor for complications after getting baseline vital signs; major reactions usually appear before the first 50 mL have been transfused.
- Check the patient's vital signs within 30 minutes prior to transfusion, 15 minutes after initiating the transfusion, after the transfusion is completed, 1 hour after the transfusion has been completed, and as needed based on clinical observation of the patient's condition.

Table 41-10 Transfusion Reactions

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

REACTION	SIGNS AND SYMPTOMS	NURSING ACTIVITY
Allergic reaction: allergy to transfused blood	Hives, itching Anaphylaxis	• Stop transfusion immediately and keep vein open with normal saline. • Notify health care team immediately. • Administer antihistamine parenterally as necessary.
Febrile reaction: fever develops during infusion	Fever and chills Headache Malaise	• Stop transfusion immediately and keep vein open with normal saline. • Notify health care team. • Treat symptoms.
Hemolytic transfusion reaction: incompatibility of blood product	Immediate onset Facial flushing Fever, chills Headache Low back pain Shock	• Stop infusion immediately and keep vein open with normal saline. • Notify health care team immediately. • Obtain blood samples from site. • Obtain first voided urine. • Treat shock if present. • Send unit, tubing, and filter to lab. • Draw blood sample for serologic testing and send urine specimen to lab.
Circulatory overload: too much blood administered	Dyspnea Dry cough Pulmonary edema	• Slow or stop infusion. • Monitor vital signs. • Notify health care team. • Place in upright position with feet dependent.
Bacterial reaction: bacteria present in blood	Fever Hypertension Dry, flushed skin Abdominal pain	• Stop infusion immediately. • Obtain culture of patient's blood and return blood bag to lab. • Monitor vital signs. • Notify health care team. • Administer antibiotics as prescribed.

- Increase the transfusion rate after 15 minutes when there are no signs of a reaction and to ensure completion of the transfusion within 4 hours.
- Assess the patient for any adverse reactions at least every 30 minutes throughout the transfusion.
- Stop the transfusion immediately if signs and symptoms of a transfusion reaction are present (Table 41-10); notify the prescriber and follow facility policy for additional reporting. Be prepared to administer emergency medications as prescribed.
- Monitor the patient to detect febrile or pulmonary transfusion reactions for at least 4 to 6 hours; educate patients who are not under direct observation after their transfusion about signs and symptoms of delayed transfusion reaction and the importance of reporting.

Consult facility policy regarding the length of time blood or a blood product must be returned after it is obtained from the blood bank/source. Nurses are responsible for monitoring the patient for adverse reactions to the blood transfusion. Short- and long-term complications can occur and ongoing nursing assessment and intervention are a critical part of management of transfusion of blood and blood products (Carman et al., 2018).

Administering Parenteral Nutrition

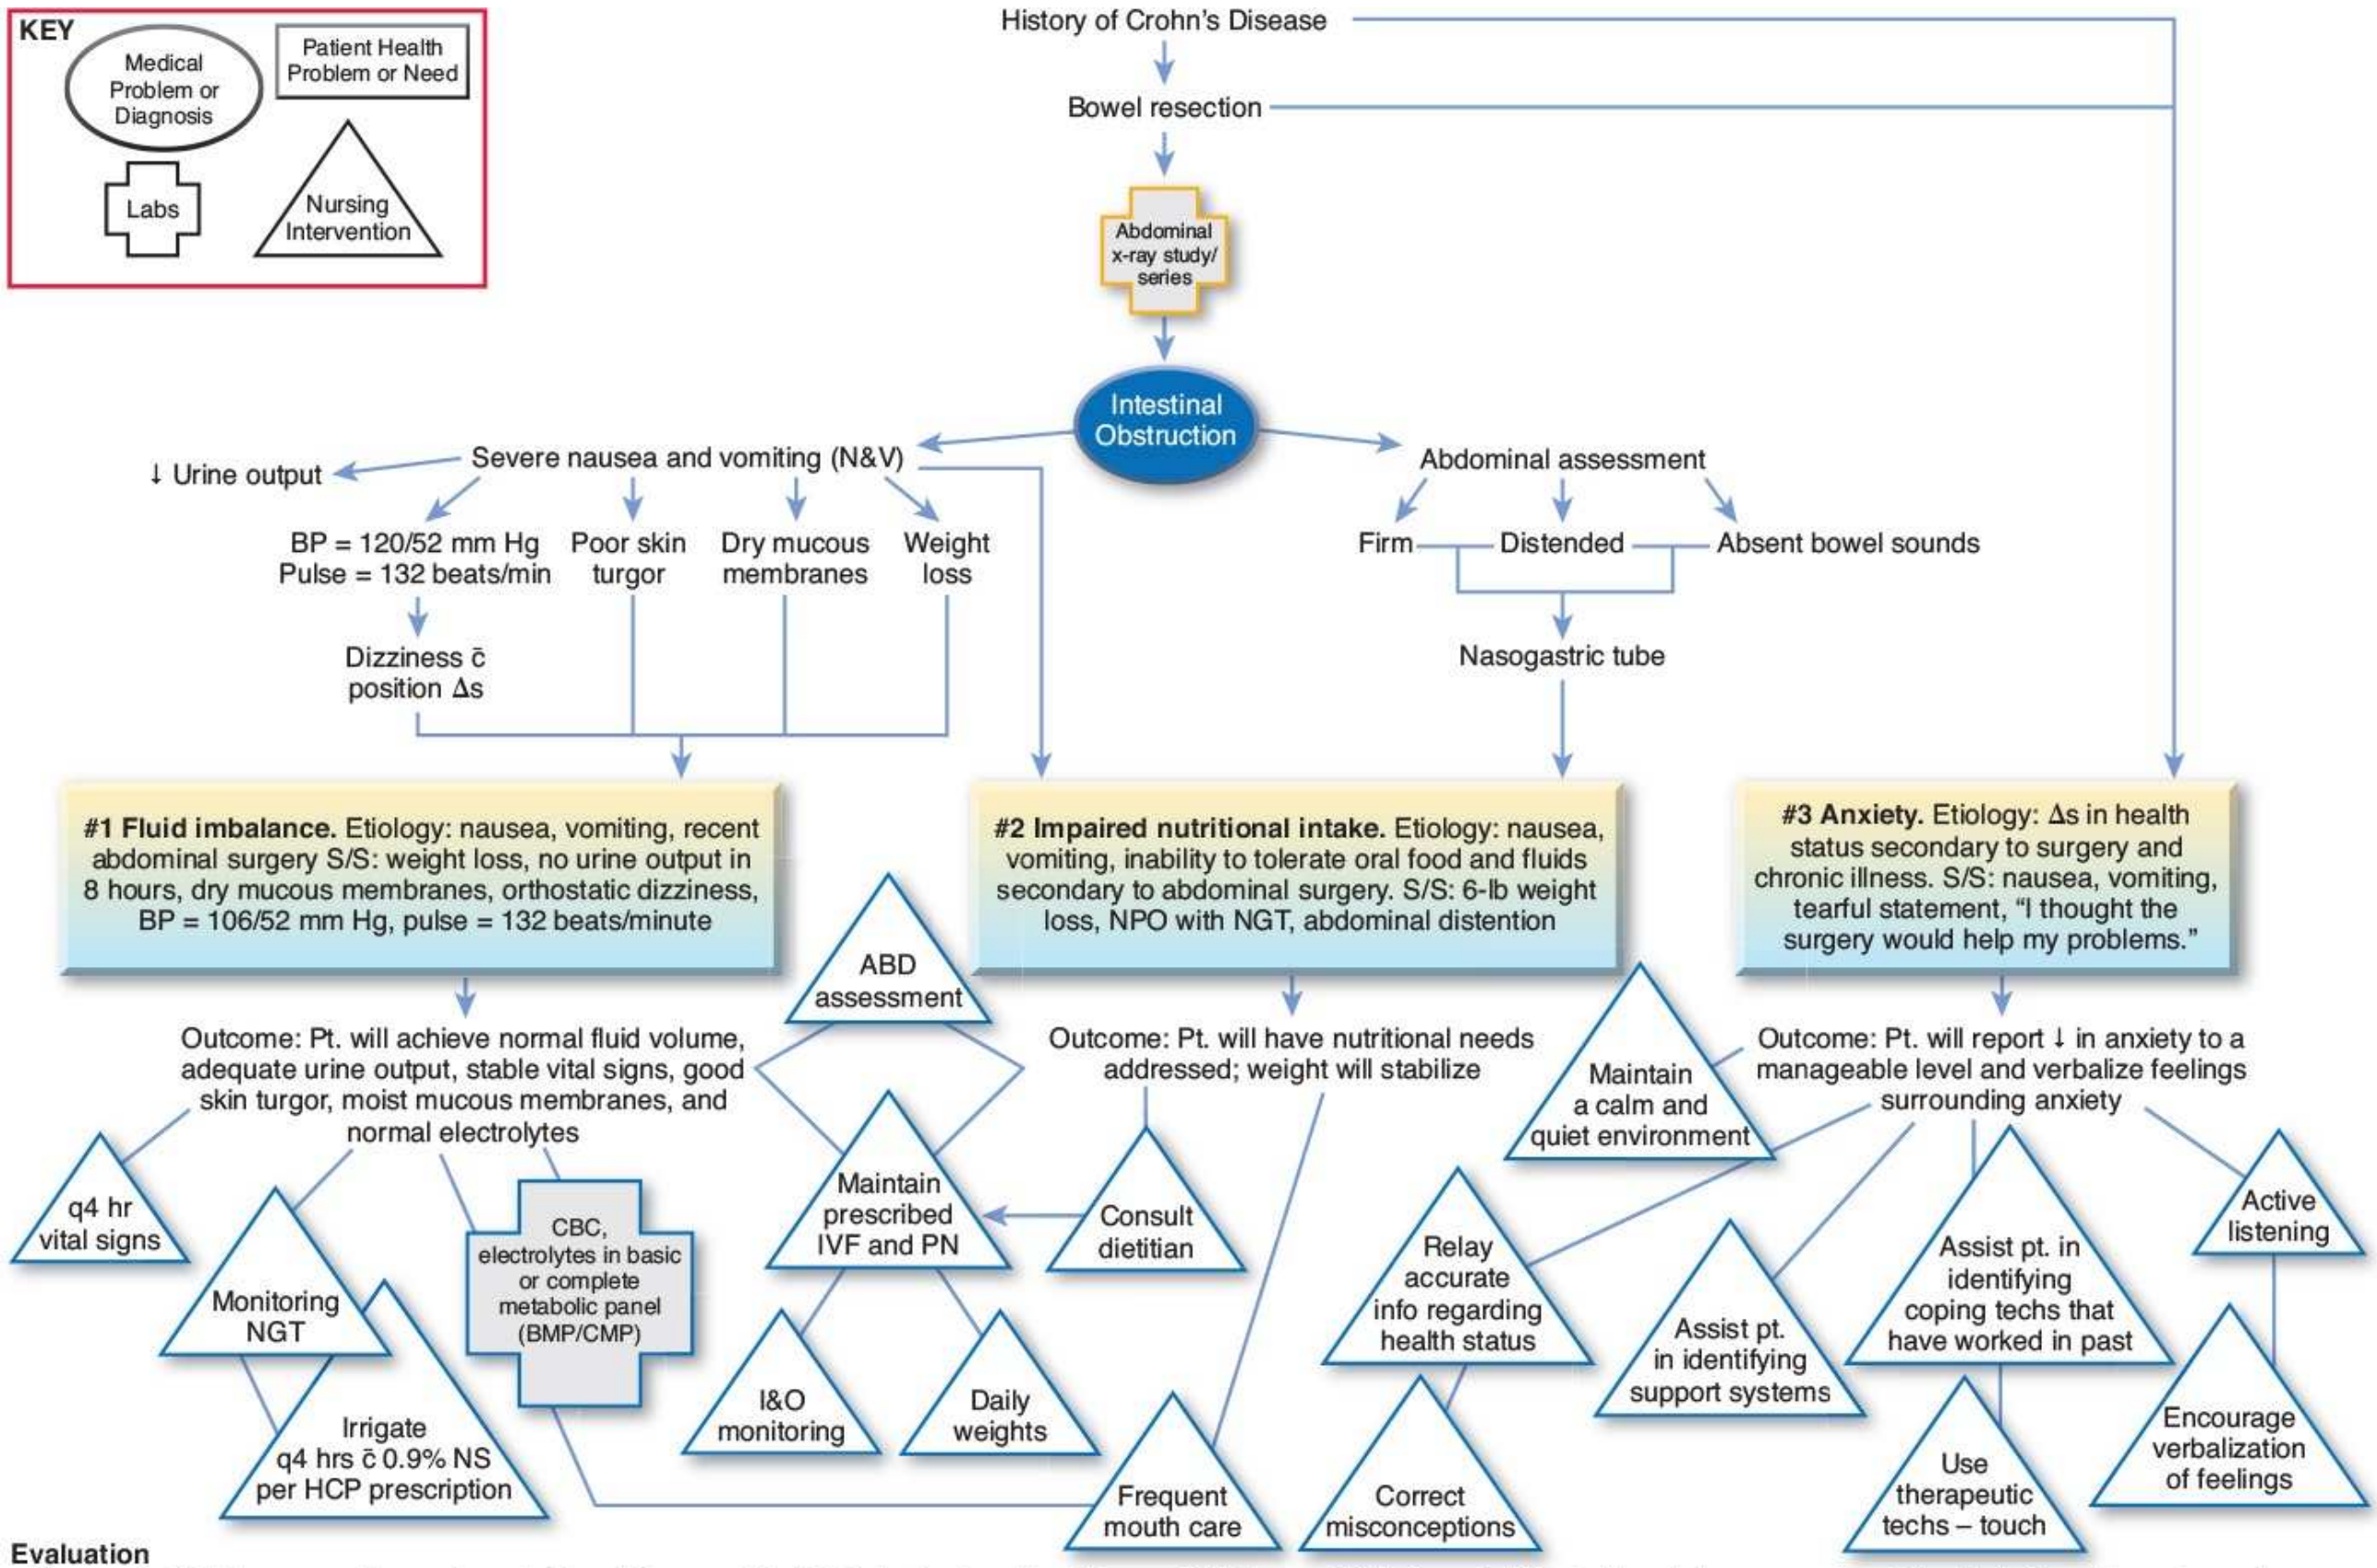
Parenteral nutrition (PN) is the administration of nutritional support via the IV route. Patients who cannot meet their nutritional needs by the oral or enteral routes may require IV nutritional supplementation. IV supplementation may be prescribed for a variety of patients, such as patients at high risk for malnutrition in specific circumstances or when enteral nutrition is not feasible or sufficient to meet the patient's energy needs or protein goals (McClave et al., 2016).

PN is a highly concentrated, hypertonic nutrient solution that can be administered centrally through a central venous access device. A less concentrated nutrient solution is sometimes prescribed for a patient and is administered through a short-term IV access in a peripheral vein (peripheral parenteral nutrition [PPN]). The basic difference between the two types is the concentration of the solutions infused. Assess for potential complications of PN such as catheter-related infection and electrolyte imbalances. Parenteral nutrition is discussed in Chapter 37 in further detail, including the procedure for PN administration and related nursing responsibilities.

Evaluating

Ongoing evaluation of the plan of care is integral. Collaborate with the health care team and the patient and family/caregivers to evaluate and readjust the plan of care and interventions. Refer to the accompanying concept map for an illustration of the nursing process for Grace Gillian. Evaluate the effectiveness of the plan of care to promote healthy fluid, electrolyte, and acid–base balance based on the following parameters:

- Is the patient making progress toward meeting identified outcomes related to fluid, electrolyte, and acid–base balance?
- Are the patient's drinking and eating patterns supplying the needed fluid and electrolytes?
- Is the patient having any difficulties with oral fluids, tube feedings, IV therapy, or PN?
- Is the patient's urine output about equal to the fluid intake? Do the patient's weight and record of fluid intake and output indicate fluid balance?
- Are abnormal sources of fluid loss (e.g., vomiting, diarrhea, draining wounds, fistula) responding to prescribed interventions? Are the signs of fluid volume deficit improving?
- Are the signs and symptoms that initially manifested the fluid, electrolyte, or acid–base imbalances absent or improved? Has therapy led to any troublesome new signs or symptoms?
- Is the patient now able to practice self-care behaviors to maintain fluid, electrolyte, and acid–base balance? Can the patient describe appropriate responses to potential future problems?



This evaluation should be ongoing as the plan of care is implemented. As the patient achieves the expected outcomes, these should be noted and reinforced. Before nursing care is terminated, the patient and family/caregivers should be able to independently promote fluid, electrolyte, and acid–base balance.

REFLECTIVE PRACTICE LEADING TO PERSONAL LEARNING

Remember that the goal of reflective practice is to look at an experience, understand it, and learn from it. As you begin to develop expertise in implementing measures related to fluid, electrolyte and acid–base balance, reflect on your experiences—successes and failures—in order to improve your practice. How can you do it better next time? What did you learn today that can help you tomorrow? Begin your reflection by paying close attention to the following while performing interventions and providing nursing care related to fluid, electrolyte and acid–base balance:

- Did your preparation and practice related to performing interventions related to fluid, electrolyte, and acid–base balance result in your feeling confident in your ability to provide care? Did your competence and confidence inspire the patient's and family/caregiver's trust?
- How did you prioritize the data you collected? What patterns in the data did you identify? What knowledge from your learning, personal experience and intuition did you use to make decisions and develop your plan of care?
- How confident are you that the data you communicated and recorded related to fluid, electrolyte, and acid–base balance accurately communicate the health status, health problems, issues, risks, and strengths of the patient? How successfully have you communicated this information to other members of the health care team?
- Were you aware of any cultural and/or ethnic beliefs or practices that may have influenced the patient's personal practices impacting fluid, electrolyte, and acid–base balance? Were you aware of any stereotypes or prejudices that might have negatively influences the clinical encounter? If so, how did you address these?
- Was the patient/family/caregiver participation in the process at an optimal level? How might you have better engaged the patient and family/caregivers?
- Did the patient/family/caregivers know your name, and know what to expect of you and nursing? Did the patient sense that you are respectful, caring, and competent to provide care?

Perhaps the most important questions to reflect on are: Are your patients and their families/caregivers better for having had *you* share in the critical responsibility of partnering with them to address their fluid, electrolyte, and acid–base balance needs? Are your patients now receiving thoughtful, person-centered, prioritized, holistic, evidence-based treatment and care because of your efforts?

Evaluation

- **Diagnosis #1** Intravenous therapy is maintained. Grace voided 250 mL of urine after 4 hours of IV therapy. Vital signs stabilized. Her abdomen remains distended without bowel sounds. A surgical consult was prescribed to evaluate the need for abdominal surgery.
- **Diagnosis #2** Grace's abdomen remains distended with absent bowel sounds. She remains NPO and is being evaluated for surgery. Collaborate with dietitian and physician to determine need for TPN.
- **Diagnosis #3** Grace verbalizes and understanding of rationales for interventions. She is participating in the plan of care and asking questions regarding plan of care.

Skill 41-1

Initiating a Peripheral Intravenous Catheter Access and Intravenous Infusion

Delegation Guidelines

The initiation of a PIVC and IV infusion is not delegated to assistive personnel (AP). Depending on the state's nurse practice act and the organization's policies and procedures, initiation of a PIVC and IV infusion may be delegated to licensed practical/vocational nurses (LPN/LVNs). The decision to delegate must be based on careful analysis of the patient's needs and circumstances as well as the qualifications of the person to whom the task is being delegated. Refer to the Delegation Guidelines in Appendix A.

EQUIPMENT

- IV solution, as prescribed
- Electronic MAR (eMAR) or medication administration record (MAR)
- Towel or disposable pad
- Nonallergenic tape
- IV administration set
- Label for infusion set (for next change date)
- Transparent semipermeable membrane (TSM) dressing
- Electronic infusion device (if appropriate)
- Tourniquet
- Time tape and/or label (for IV container)
- Cleansing swabs (>0.5% chlorhexidine in alcohol solution is preferred; tincture of iodine, an iodophor [povidone-iodine], or 70% alcohol may also be used) (Gorski et al., 2021; Mimoz et al., 2015; O'Grady et al., 2017)
- IV securement/stabilization device, as appropriate
- Clean gloves
- Additional PPE, as indicated
- IV pole
- Local anesthetic (based on facility policy and/or if prescribed)
- PIVC
- Short extension tubing, if not permanently attached to the PIVC
- Needleless connector or end cap for extension tubing
- Antimicrobial wipes
- Passive disinfection caps (based on facility policy)
- Skin barrier protectant wipe (e.g., Skin-Prep®)
- Single-use clippers or scissors for hair removal (as indicated)
- Single-use, commercially prepared, prefilled syringe with sterile normal saline for injection, minimum volume equal to twice the internal volume of the catheter system (Gorski et al., 2021), according to facility policy.

IMPLEMENTATION

ACTION	RATIONALE
1. Verify the prescribed IV solution on the eMAR/MAR. Consider the appropriateness of the prescribed therapy in relation to the patient. Clarify any inconsistencies. Check the patient's health record for allergies. Know techniques for IV insertion, precautions, and the purpose of the IV solution administration, if prescribed. Check the solution for color and the container for leaking and expiration date, if prescribed. Gather the necessary supplies.	This ensures that the correct IV solution and rate of infusion and/or medication will be administered. The nurse is responsible for critically evaluating all prescribed interventions prior to administration. Any concerns regarding the type or amount of therapy prescribed should be immediately and clearly communicated to the prescribing health care provider. This knowledge and skill are essential for safe and accurate IV and medication administration. Preparation promotes efficient time management and an organized approach to the task.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

 2. Perform hand hygiene and put on PPE, if indicated.	Hand hygiene and PPE prevent the spread of microorganisms. PPE is required based on transmission precautions.
 3. Identify the patient.	Identifying the patient ensures the right patient receives the intervention and helps prevent errors.
4. Assemble equipment on the bedside stand or overbed table or other surface within reach.	Bringing everything to the bedside conserves time and energy. Arranging items nearby is convenient, saves time, and avoids unnecessary stretching and twisting of muscles on the part of the nurse.
5. Close the curtains around the bed and close the door to the room, if possible. Explain to the patient what you are going to do and why. Ask the patient about allergies to medications, tape, or skin antiseptics, as appropriate. If considering using a local anesthetic, inquire about allergies for these substances as well. Consider use of nonpharmacologic interventions to reduce pain associated with PIVC insertion.	This ensures the patient's privacy. Explanation relieves anxiety and facilitates engagement. Possible allergies may exist related to medications, tape, or local anesthetic. Injectable anesthetic can result in allergic reactions and tissue damage. Nonpharmacologic interventions suggested for use to reduce PIVC insertion–related pain and discomfort include distraction, relaxation, breathing exercises, and virtual reality (VR) (Basak et al., 2020; Gorski et al., 2021). The choices of interventions for pediatric patients include swaddling, breastfeeding, pacifiers, rocking, blowing bubbles, reading books, use of VR, and local vibrating cold devices and should be made with consideration of growth and development level (Gorski et al., 2021).
6. If using a local anesthetic, explain the rationale and procedure to the patient. Apply the anesthetic to a few potential insertion sites. Allow sufficient time for the anesthetic to take effect.	Explanations provide reassurance and facilitate engagement. Local anesthetic agents should be used to reduce pain in all adult and pediatric populations (Gorski et al., 2021). Local anesthetic agents to reduce pain associated with PIVC insertion include vapocoolant sprays, topical transdermal agents, jet injection of pressure-accelerated lidocaine (needle-free), application of hot or cold to the site, and intradermal injection of lidocaine or bacteriostatic 0.9% sodium chloride (Gorski et al., 2021; Korkut et al., 2020; Welyczko, 2020). Some anesthetics take up to an hour to become effective.
Prepare the IV Solution and Administration Set	
7. Compare the IV container label with the eMAR/MAR. Remove the IV bag from the outer wrapper, if indicated. Check expiration dates. Scan the bar code on container, if necessary. Compare the patient identification band with the eMAR/MAR. Alternatively, label the solution container with the patient's name, solution type, additives, date, and time. Complete a time strip for the infusion and apply to the IV container.	Checking the label with eMAR/MAR ensures the correct IV solution will be administered. Identifying the patient ensures the right patient receives the medications and helps prevent errors. The time strip allows for quick visual reference by the nurse to monitor infusion accuracy.
8. Maintain aseptic technique when opening sterile packages and the IV solution. Remove the administration set from the package (Figure 1). Apply the label to the tubing reflecting the day/date for the next set change, per facility guidelines.	Asepsis is essential for preventing the spread of microorganisms. Labeling the tubing ensures adherence to facility policy regarding administration set changes and reduces the risk of the spread of microorganisms. Refer to Table 41-8 for recommended administration set change guidelines.

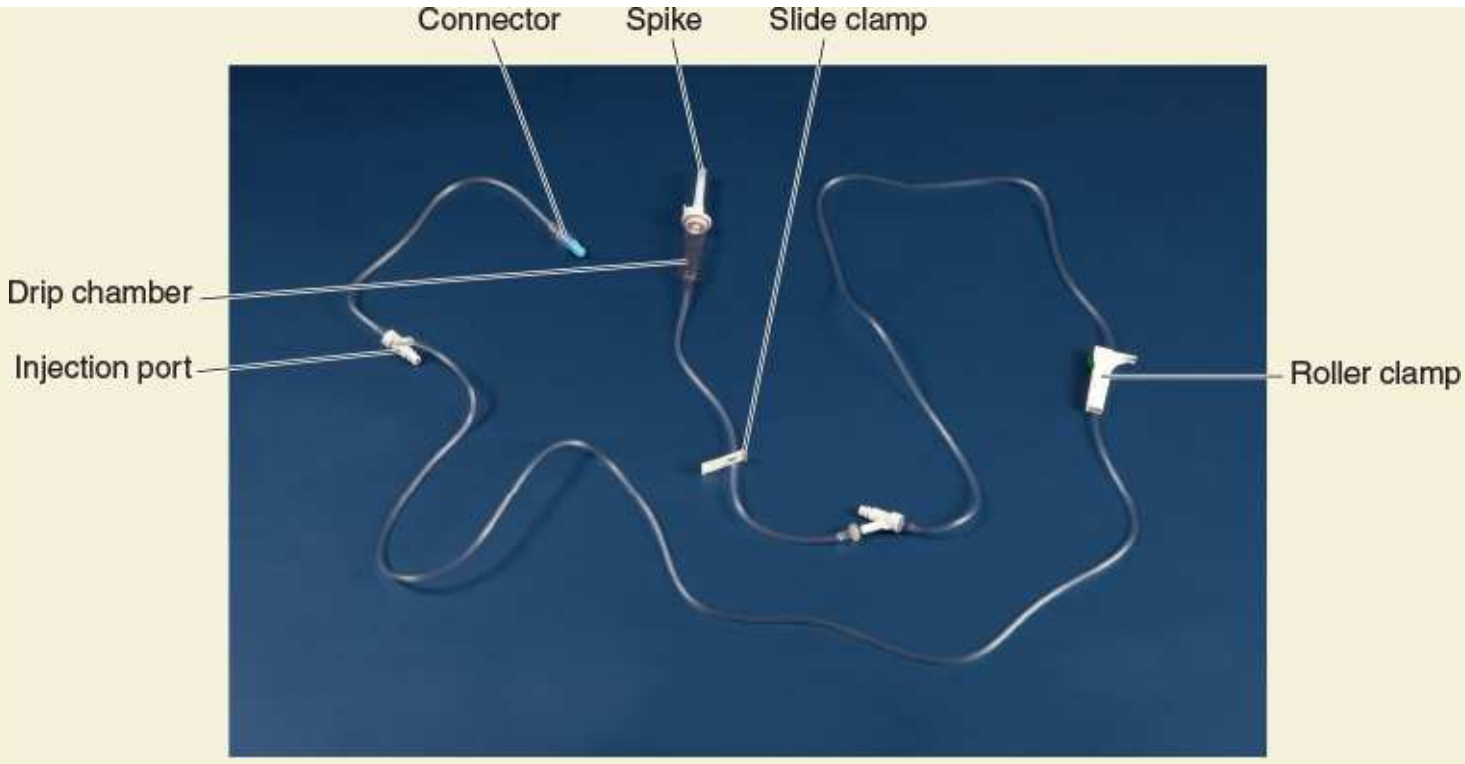

FIGURE 1. Basic administration set for gravity/free-flow infusion.

9. Close the roller clamp or slide the clamp on the IV administration set (Figure 2). Invert the IV solution container and remove the cap on the entry site, taking care not to touch the exposed entry site. Remove the cap from the spike on the administration set. Using a twisting and pushing motion, insert the administration set spike into the entry site of the IV container (Figure 3). Alternatively, follow the manufacturer's directions for insertion.

Clamping the IV tubing prevents air and fluid from entering the IV tubing.

Inverting the container allows easy access to the entry site. Touching the opened entry site on the IV container and/or the spike on the administration set results in contamination, resulting in the need to discard the container/administration set. Inserting the spike punctures the seal in the IV container and allows access to the contents.

FIGURE 2. Closing clamp on administration set.

FIGURE 3. Inserting administration set spike into entry site of IV fluid container.

10. Hang the IV container on the IV pole. Squeeze the drip chamber and fill it at least halfway (Figure 4).

Suction causes fluid to move into the drip chamber. Fluid prevents air from moving down the tubing.

FIGURE 4. Squeezing drip chamber to fill at least halfway.

FIGURE 5. Priming administration set.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

11. Open the IV tubing clamp and allow fluid to move through the tubing. Follow the additional manufacturer's instructions for the specific electronic infusion pump, as indicated. **Allow fluid to flow until all air bubbles have disappeared, and the entire length of the tubing is primed (filled) with IV solution (Figure 5).** Close the clamp. Alternatively, some brands of tubing may require removal of the cap at the end of the IV tubing to allow the fluid to flow. Maintain its sterility. After the fluid has filled the tubing, recap the end of the tubing.	This technique prepares for IV fluid administration and removes air from the tubing. Air should be purged from all administration sets to prevent air embolism (Gorski et al., 2021). Touching the open end of the tubing results in contamination, resulting in the need to discard the administration set.

FIGURE 6. Inserting administration set into electronic infusion device.

12. If an electronic device is to be used, follow the manufacturer's instructions for inserting the tubing into the device (Figure 6).	This ensures proper use of equipment.

Initiate Peripheral Venous Access

13. Place the patient in the low-Fowler position in bed. Place a protective towel or pad under the patient's arm.	The supine position permits either arm to be used and allows for good body alignment. The towel protects the underlying surface from blood contamination.
14. Provide emotional support, as needed.	The patient may experience anxiety because they may, in general, fear needlestick or IV infusion.
15. Open the short extension tubing package. Attach the needleless connector or end cap, if not in place. Clean the needleless connector or end cap with an alcohol wipe. Insert a syringe with normal saline into the extension tubing. Fill the extension tubing with normal saline and place the extension tubing and syringe back on the package, within easy reach.	A needleless connector should be attached to the extension tubing to eliminate the use of needles when connecting to the VAD (Gorski et al., 2021). Priming the extension tubing removes air from the tubing and prevents administration of air when connected to venous access. Having the tubing within easy reach facilitates accomplishment of procedure.
16. Select and palpate for an appropriate vein. Refer to the guidelines in the previous Assessment section. If the intended insertion site is visibly soiled, clean the area with soap and water (Gorski et al., 2021).	The use of an appropriate vein decreases discomfort for the patient and reduces the risk for damage to body tissues.
17. Remove excess hair at the insertion site, if needed, to facilitate application of the site dressing. Use single-patient-use scissors or disposable-head surgical clippers to remove hair at the insertion site and dressing area.	Hair can inhibit adhesion of the site dressing. Shaving causes microabrasions and may increase the risk for infection (Gorski et al., 2021).
18. Put on gloves.	Gloves prevent contact with blood and body fluids.
19. Apply a single-patient-use tourniquet (Gorski et al., 2021) 3 to 4 inches above the venipuncture site to obstruct venous blood flow and distend the vein	A single-patient-use tourniquet prevents transmission of microorganisms. Impeding venous blood flow causes the vein to distend while maintaining arterial

(Figure 7). Direct the ends of the tourniquet away from the entry site. Make sure the radial pulse is still present.

circulation. Distended veins are easy to see, palpate, and enter. The end of the tourniquet could contaminate the area of injection if directed toward the entry site. The tourniquet may be applied too tightly, so assessment for the radial pulse is important. Checking radial pulse ensures arterial supply is not compromised.

FIGURE 7. Applying tourniquet.

20. Instruct the patient to hold their arm lower than their heart.	Lowering the arm below the heart level helps distend the veins by filling them.
21. Ask the patient to open and close their fist. Observe and palpate for a suitable vein. If a vein cannot be felt, consider the use of vascular visualization technology or ultrasound to assist with identification of peripheral veins (Gorski et al., 2021).	Contracting the muscles of the forearm forces blood into the veins, thereby distending them further. Vascular visualization technology can be used to assist with identification of peripheral veins, with resulting increased insertion success; reduced insertion-related complications; and minimization of the need to escalate to unnecessary, more invasive VADs (Gorski et al., 2021). Ultrasound-guided PIVC insertion is a safe, efficient intervention and should be used for placement of a short PIVC in difficult-to-access adult patients (Gorski et al., 2021; Houston, 2013), the insertion of long PIVCs (Gorski et al., 2021), and after failed venipuncture attempts (Edwards & Jones, 2018; Egan et al., 2013).
22. Use a single-use sterile applicator containing sterile antiseptic solution to **cleanse the site with >5% chlorhexidine in alcohol solution or the solution identified by facility policy. Follow the manufacturer's directions for use to determine the product application process and dry times** (Gorski et al., 2021). **Allow the antiseptic to dry naturally; do not wipe, fan, or blow on the skin** (Gorski et al., 2021).	Cleansing is necessary because organisms on the skin can be introduced into the tissues or the bloodstream with the needle. Use of >0.5% chlorhexidine in alcohol solution is preferred for skin antisepsis (Gorski et al., 2021; Sarani et al., 2018). If there is a contraindication to alcoholic chlorhexidine solution, tincture of iodine, an iodophor (povidone-iodine), or 70% alcohol may instead be used (Gorski et al., 2021; Mimoz et al., 2015; O'Grady et al., 2017).
23. **Do not touch/palpate the insertion site after skin antisepsis. Use sterile gloves if repalpation of the vein is necessary after skin antisepsis.**	Touching the site after skin antisepsis recontaminates the insertion site. Use of sterile gloves for palpation prevents contamination of the insertion site.
24. Using your nondominant hand placed about 1 or 2 inches below the entry site, hold the patient's skin taut against the vein. **Avoid touching the prepared site.** Ask the patient to remain still while performing the venipuncture.	Pressure on the vein and surrounding tissues stabilizes the vein and helps prevent movement of the vein as the needle or catheter is being inserted. The planned IV insertion site is not palpated after skin cleansing unless sterile gloves are worn to prevent contamination (Gorski et al., 2021). Patient movement may prevent proper technique for IV insertion.
25. Align the IV catheter on top of the vein; enter the	This allows the needle or catheter to enter the vein with

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

skin gently, holding the catheter by the hub in your dominant hand, bevel side up, at a 10- to 15-degree angle (Figure 8). Insert the catheter from directly over the vein or from the side of the vein. While following the course of the vein, advance the needle or catheter into the vein. A sensation of "give" can be felt when the needle enters the vein.

minimal trauma and deters passage of the needle through the vein.

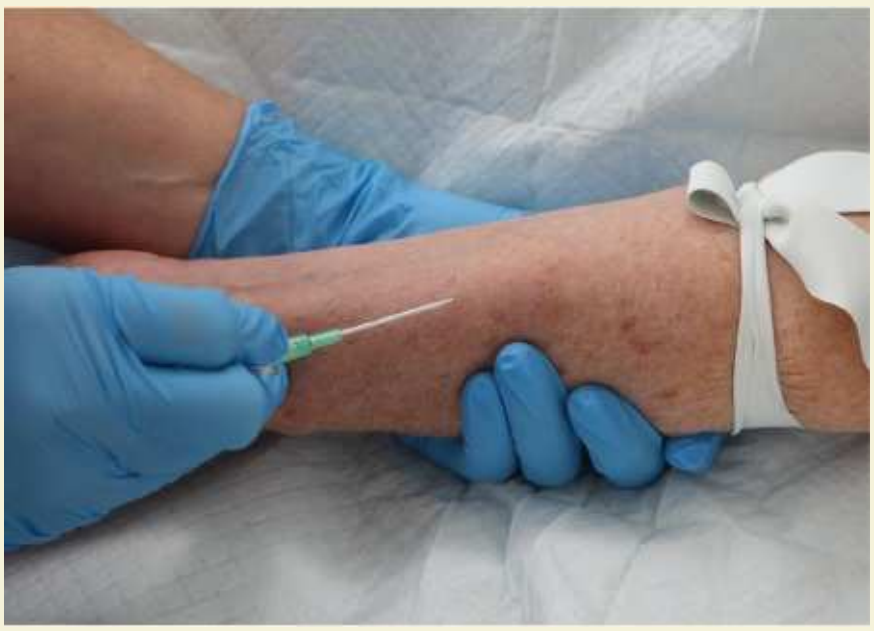

FIGURE 8. Stretching skin taut and inserting needle.

26. Continue to hold the skin taut. When blood returns through the catheter and/or the flashback chamber of the catheter, use the push-off tab to separate the catheter from the needle stylet and advance the catheter into the vein until the hub is at the venipuncture site. The exact technique depends on the type of device used.	The tourniquet causes increased venous pressure, resulting in automatic backflow. Placing the access device well into the vein helps to prevent dislodgment.
27. Release the tourniquet. Activate the safety mechanism on the needle stylet. Compress the skin well above the catheter tip to stop the flow of blood. Quickly remove the protective cap from the extension tubing, attach it to the catheter hub, and tighten the Luer lock. Stabilize the catheter or needle with your nondominant hand.	Bleeding is minimized and the patency of the vein is maintained if the connection is made smoothly between the catheter and extension tubing.
28. Continue to stabilize the catheter or needle and pull back on the syringe to assess for blood return, then flush gently with the saline, observing the site for infiltration and leaking. Remove the syringe from the end cap.	Presence of a blood return upon aspiration and lack of resistance when flushing indicate patency of the VAD (Gorski et al., 2021). Infiltration and/or leaking and the patient reports of pain and/or discomfort indicate that the insertion into the vein is not successful and should be discontinued. The syringe is no longer needed once flushing is complete.
29. Open the skin protectant wipe. Apply the skin protectant to the site, making sure to apply—at a minimum—the area to be covered with the dressing. Place a sterile transparent dressing and/or catheter securing/stabilization device over the venipuncture site. Loop the tubing near the entry site, and anchor it with tape (nonallergenic) close to the site.	The skin protectant aids in adhesion of the dressing and decreases the risk for skin trauma when the dressing is removed. A transparent dressing allows easy visualization and protects the site. Stabilization/securing devices preserve the integrity of the access device, minimize catheter movement at the hub, and prevent catheter dislodgement and loss of access (Gorski et al., 2021). Some stabilization devices also act as a site dressing. The weight of the tubing is sufficient to pull it out of the vein if it is not well anchored. Nonallergenic tape is less likely to tear fragile skin.
30. Label the IV dressing with the date, time, site, and type and size of the catheter placed (Figure 9).	Other personnel working with the infusion will know the site, type of device being used, and when it was

inserted.

FIGURE 9. Venous access site with labeled dressing.

31. Using an antimicrobial swab, vigorously disinfect the connection surface and sides of the needleless connector or end cap on the extension tubing and allow it to dry. Remove the end cap from the administration set. Insert the end of the administration set into the needleless connector or end cap (Figure 10). Loop the administration set tubing near the entry site, and anchor it with tape (nonallergenic) close to the site. Remove your gloves. Perform hand hygiene.

    Venous access device (VAD) administration set entry points, end caps, and needleless connectors must be disinfected prior to each access to reduce the risk for introduction of microorganisms and prevent VAD-related infection (Frimpong et al., 2015; Gorski et al., 2021; Harper, 2014; Loveday et al., 2014). Friction is needed to physically remove microorganisms from the top, sides, and threads of the needleless connector or end cap. Allow the antiseptic to dry completely following the manufacturer's directions for use (Gorski et al., 2021). Inserting the administration set allows initiation of the fluid infusion. The weight of the tubing is sufficient to pull it out of the vein if it is not well anchored. Nonallergenic tape is less likely to tear fragile skin. Removing gloves properly reduces the risk for infection transmission and contamination of other items. Hand hygiene prevents transmission of microorganisms.

FIGURE 10. Inserting administration set into the end cap of venous access device.

32. Open the clamp on the administration set. Set the flow rate and begin the fluid infusion (Figure 11). Alternatively, start the flow of solution by releasing the clamp on the tubing and counting the drops. Adjust until the correct drop rate is achieved. Assess

    Verifying the rate and device settings ensures the patient receives the correct volume of solution. If the catheter slips out of the vein, the solution will accumulate (infiltrate) into the surrounding tissue.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

the flow of the solution and function of the infusion device. Inspect the insertion site for signs of infiltration (Figure 12).

FIGURE 11. Initiating IV fluid infusion.

FIGURE 12. Inspecting insertion site.

33. Apply an IV securement/stabilization device if not already in place as part of the dressing, as indicated, based on facility policy. Explain to the patient the purpose of the device and the importance of safeguarding the site when using the extremity.

These systems are recommended for use on all venous access sites, particularly central venous access sites, to preserve the integrity of the access device, minimize catheter movement at the hub, and prevent catheter dislodgement and loss of access (Gorski et al., 2021). Some devices also act as a site dressing and may already have been applied.

34. Apply a passive disinfection cap to each access site on the administration set; use an antimicrobial swab to vigorously disinfect the connection surface and sides of each access site and allow it to dry. Attach a passive disinfection cap to each site (Figure 13).

Passive disinfection caps contain an antiseptic-impregnated sponge that dispenses the antiseptic over the connector's top and threads and protects the hub from contamination by touch or airborne sources (Gorski et al., 2021; Stango et al., 2014). VAD administration set entry points, end caps, and needleless connectors must be vigorously scrubbed and disinfected prior to each access to reduce the risk for introduction of microorganisms and prevent VAD-related infection (Frimpong et al., 2015; Gorski et al., 2021; Harper, 2014; Loveday et al., 2014). Friction is needed to physically remove microorganisms from the top, sides, and threads of the needleless connector or end cap. Allow the antiseptic to dry completely to ensure complete effectiveness.

FIGURE 13. Attaching a passive disinfection cap to each access site.

35. Remove the equipment and return the patient to a

Positioning promotes patient comfort and safety.

position of comfort. Lower the bed, if it is not in the lowest position.

36. Remove additional PPE, if used. Perform hand hygiene.

Proper removal of PPE reduces the risk for infection transmission and contamination of other items. Hand hygiene prevents transmission of microorganisms.

37. Return to check the flow rate and observe the IV site for infiltration and/or other complications 30 minutes after starting the infusion and at least hourly thereafter. Ask the patient if they are experiencing any pain or discomfort related to the IV infusion.

Continued monitoring is important to maintain the correct flow rate. Early detection of problems ensures prompt intervention.

Documentation

Guidelines

Document the date and time of insertion, number of attempts, and location (anatomical descriptors, laterality, landmarks) where the IV access was placed as well as the type, length and gauge/size of the PIVC inserted, type of anesthetic (if used), type of IV solution, rate of the IV infusion (often done in the eMAR/MAR), and the use of a securing or stabilization device. Document the use of visualization technology (if used). Document the condition of the site. Record the patient's reaction to the procedure and pertinent patient teaching, such as alerting the nurse if the patient experiences any pain from the IV or notices any swelling at the site. Document the IV fluid solution on the intake and output record.

Sample Documentation

Practice documenting peripheral venous access infusion in *Lippincott DocuCare*.

11/02/25 0830 20-gauge IV started in dorsal surface of the L forearm via the cephalic vein; positive blood return, lack of resistance when flushed. Transparent dressing and peripheral stabilization device applied. Site without redness, drainage, or edema; patient denies discomfort. $D_5$1/2 NS with 20 mEq KCl begun at 110 mL/hr. Patient instructed to call with any pain, discomfort, or swelling and verbalizes an understanding of instructions.

—S. Barnes, RN

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

UNEXPECTED SITUATIONS AND ASSOCIATED INTERVENTIONS

- *An artery is inadvertently accessed or the patient reports paresthesias, numbness, or tingling upon insertion:* Immediately remove the catheter, apply pressure to the insertion site, and notify the health care team (Gorski et al., 2021).
- *Fluid does not easily flow into the vein:* Reposition the extremity because certain positions that the patient may assume may prevent the IV from infusing properly. If the IV is a free-flowing IV, raise the height of the IV pole. This may promote an increase in IV flow. Attempt to flush the PIVC with saline. Check the IV connector to ensure that the clamp is fully open. If fluid still does not flow easily, or if resistance is met while flushing, the IV may be against a valve and may need to be restarted in a different location.
- *Fluid does not flow easily into the vein, and the skin around the insertion site is edematous and cool to the touch:* The IV has infiltrated. Put on gloves and remove the catheter. Use a skin marker to outline the area with visible signs of infiltration to allow for assessment of changes (Gorski et al., 2021). Secure the gauze with tape over the insertion site without applying pressure. Assess the area distal to the VAD for capillary refill, sensation, and motor function Gorski et al., 2021). Restart the IV in a new location. Estimate the volume of fluid that escaped into the tissue based on the rate of infusion and length of time since the last assessment. Notify the health care team and use an appropriate method for clinical management of the infiltrate site, based on the infused solution and facility guidelines (Gorski et al., 2021). Record the site assessment and interventions as well as the site for new venous access.
- *A small hematoma is forming at the site while you are inserting the catheter:* The vein is "blowing," which means a small hole has been made in the vein, and blood is leaking out into the tissues. Remove and discard the catheter and choose an alternative insertion site.
- *Fluids are leaking around the insertion site:* Check connections. Change the dressing on the site. If the site

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

continues to leak, remove the IV and restart it in a new location.

- *IV infusion set becomes disconnected from IV:* Discard the administration set to prevent infection. Assess patency and attempt to flush the PIVC. If the PIVC is still patent, the site may still be used as long as the catheter hub has not been contaminated.
- *IV catheter is partially pulled out of the insertion site (migrates externally):* Do not readvance the catheter. Whether the access is salvageable depends on how much of the catheter remains in the vein. Assess for proper placement in the vein before further use and consider the infusion therapy and circumstances to determine viability and secure at the current location (Gorski et al., 2021). Removal and reinsertion at a new site might be the most appropriate intervention if the PIVC is no longer in an appropriate position for the prescribed infusion (Gorski et al., 2021). If the PIVC is not removed, monitor it closely for signs of infiltration and infection.

Special Considerations

General Considerations

- The smallest-gauge PIVC that will accommodate the prescribed therapy and patient need should be selected (Gorski et al., 2021). A 20- to 24-gauge catheter is recommended for most infusions to decrease the risk of phlebitis (Gorski et al., 2021).
- A 22- to 26-gauge catheter is recommended for patients with limited venous options to minimize insertion-related trauma (Gorski et al., 2021).
- An individual nurse should not make more than two attempts at vascular access placement when initiating venous access for a patient (Gorski et al., 2021). If unsuccessful after two attempts, a colleague with advanced skills, such as a member of the nurse IV team, should attempt to initiate the venous access (Gorski et al., 2021). Multiple unsuccessful attempts cause pain to the patient and result in delayed treatment, limited future vascular access, increased costs, and increased risk for complications (Gorski et al., 2021).
- Factors that may interfere with successful evaluation of the condition of the patient's veins and subsequent placement of a peripheral catheter include obesity, diabetes, hypertension, variations in skin between patient populations (e.g., darker skin tones, excessive hair, presence of scars or tattoos), increased patient age, neonates, fluid volume deficit, injection drug use, the presence of multiple chronic health conditions (e.g., diabetes, renal disease), vascular disease, chemotherapy, and/or frequent hospitalizations (Dougherty, 2013; Dychter et al., 2012; Fields et al., 2014; Gorski et al, 2021; Morata & Bowers, 2020; Partovi-Deilami et al., 2016). These factors interfere with use of traditional techniques of direct visualization, anatomic landmarks, and palpation and make placement of the PIVC difficult (Gorski et al., 2021; Houston, 2013).
- Ultrasound-guided PIVC insertion is a safe, efficient intervention and should be used for placement of a short PIVC in difficult-to-access adult patients (Gorski et al., 2021; Houston, 2013), the insertion of long PIVCs (Gorski et al., 2021), and after failed venipuncture attempts (Edwards & Jones, 2018; Egan et al., 2013).
- Closed-system peripheral intravenous catheters are available. These systems integrate the catheter and extension tubing as one piece (Galang et al., 2020), eliminating the need for the addition of separate extension tubing, reducing potential contamination.
- Drying time with 70% isopropyl alcohol is 5 seconds; alcohol-based chlorhexidine requires 20 seconds. Povidone iodine requires longer than 6 minutes to be thoroughly dry, making it less favorable to clinical practice (Gorski et al., 2021).
- Transparent semipermeable membrane (TSM) dressings are commonly used to protect the insertion site. A gauze dressing is recommended if the patient is diaphoretic, the site is bleeding or oozing, or there is drainage from the exit site; replace it with a TSM once this is resolved (Gorski et al., 2021; O'Grady et al., 2017).
- Avoid blood pressure measurement or placement of a tourniquet over the site/upper extremity with a peripheral VAD during periods of infusion (Gorski et al., 2021).
- When the patient is showering or bathing, protect the peripheral VAD with clear plastic wrap or a device designed for this purpose. Cover the connections and protect the hub connections from water contamination (Gorski et al., 2021).

Infant and Child Considerations

- Potential sites for short PIVCs for neonates and pediatric patients include veins in the hand; forearm; and, if not walking, the foot. Avoid the antecubital fossa, which has a higher failure rate (Gorski et al., 2021). Consider veins in the forearm and the saphenous vein for long PIVCs (Gorski et al., 2021). Select an upper arm site using the basilic, cephalic, or brachial veins; veins in the leg (saphenous, popliteal, femoral) with the tip below the inguinal crease; and in the scalp with the tip in the neck, above the thorax for placement of a midline catheter (Gorski et al., 2021).
- When no alternative site is available, veins of the scalp may be used as a last resort; avoid the use of the hands, thumbs, or fingers (Gorski et al., 2021).
- A 22- to 26-gauge catheter is recommended for neonates and pediatric patients to minimize insertion-related trauma (Gorski et al., 2021).

- Use chlorhexidine with caution in infants up to age 14 days, premature infants, and low-birth-weight infants due to the risk of skin irritation and chemical burns (Gorski et al., 2021).

Older Adult Considerations

- A 22- to 26-gauge catheter is recommended for older adults to minimize insertion-related trauma (Gorski et al., 2021).
- Insert the PIVC using a 5- to 15-degree angle for older adults (Gorski et al., 2021).

Skill 41-2 Monitoring an Intravenous Site and Infusion

DELEGATION CONSIDERATIONS

The monitoring of an IV site and infusion is not delegated to assistive personnel (AP). Depending on the state's nurse practice act and the organization's policies and procedures, these procedures may be delegated to licensed practical/vocational nurses (LPN/LVNs). The decision to delegate must be based on careful analysis of the patient's needs and circumstances as well as the qualifications of the person to whom the task is being delegated. Refer to the Delegation Guidelines in Appendix A.

EQUIPMENT

- PPE, as indicated
- Standardized scale for assessing and documenting phlebitis

IMPLEMENTATION

ACTION	RATIONALE
1. Verify the IV prescribed solution on the eMAR/MAR with the health record. Consider the appropriateness of the prescribed therapy in relation to the patient. Clarify any inconsistencies. Check the patient's health record for allergies. Check solution for color and the container for leaking and expiration date. Know the purpose of the IV administration.	This ensures that the correct IV solution and rate of infusion and/or medication will be administered. The nurse is responsible for critically evaluating all prescribed interventions. Any concerns regarding the type or amount of therapy prescribed should be immediately and clearly communicated to the prescribing health care provider. This knowledge and skill are essential for safe and accurate IV and medication administration.
2. **Monitor the IV infusion every hour or per facility policy. More frequent checks may be necessary if medication is being infused.**	This promotes safe administration of IV fluids and medication.
 3. Perform hand hygiene and put on PPE, if indicated.	Hand hygiene and PPE prevent the spread of microorganisms. PPE is required based on transmission precautions.
 4. Identify the patient.	Identifying the patient ensures the right patient receives the intervention and helps prevent errors.
5. Close the curtains around the bed and close the door to the room, if possible. Explain to the patient what you are going to do and why.	This ensures the patient's privacy. Explanation relieves anxiety and facilitates engagement.
6. If an electronic infusion device is being used, check settings, alarm, and indicator lights. Check the set infusion rate (Figure 1). Note the position of fluid in the IV container in relation to the time tape. Teach the patient about the alarm features on the electronic infusion device.	Observation ensures that the infusion control device and the alarm are functioning. Lack of knowledge about "alarms" may create anxiety for the patient.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

FIGURE 1. Checking infusion device settings.

7. If the IV is infusing via gravity/free flow, check the drip chamber and time the drops (Figure 2). Refer to Guidelines for Nursing Care 41-2 to review calculation of IV flow rates for gravity/free-flow infusion.	This ensures that the flow rate is correct. Use a watch with a second hand for counting the drops in regulating a gravity/free-flow drip IV infusion.
8. Check the tubing for anything that might interfere with the flow (Figure 3). Be sure the clamps are in the open position.	Any kink or pressure on the tubing may interfere with the flow.

FIGURE 2. Checking drip chamber and timing drops.

FIGURE 3. Checking tubing for anything that might interfere with flow rate.

9. Observe the dressing for leakage of the IV solution.	Leakage may occur at the connection of the tubing with the hub of the catheter and allow for loss of the IV solution.
10. Inspect the site for swelling, leakage at the site, coolness, or pallor, which may indicate infiltration (Figure 4). Ask if the patient is experiencing any pain or discomfort. If any of these symptoms are present, the IV will need to be removed and restarted at another site. Check facility policy for treating infiltration. Refer to Table 41-9.	The catheter may become dislodged from the vein, and IV solution may flow into the subcutaneous tissue.

FIGURE 4. Inspecting IV site.

11. Inspect the site for redness, swelling, and heat. Palpate for induration. Ask if the patient is experiencing pain. These findings may indicate phlebitis, making it necessary to discontinue and restart the IV at another site. Grade phlebitis. Refer to Table 41-9 and Box 41-1. Check facility policy for treatment of phlebitis.	Chemical irritation, mechanical trauma, and microorganisms may cause injury to the vein and can lead to phlebitis.
12. Check for local manifestations (redness, pus, warmth, induration, and pain) that may indicate an infection is present at the site. Also check for systemic manifestations (chills, fever, tachycardia, hypotension) that may accompany local infection at the site. If signs of infection are present, discontinue the IV and notify the health care team. Be careful not to disconnect the IV tubing when putting on the patient's hospital gown or assisting the patient with movement to avoid contamination.	Poor aseptic technique may allow bacteria to enter the catheter insertion site or the tubing connection and may occur with manipulation of equipment.
13. Be alert for additional complications of IV therapy, such as fluid overload or bleeding. Refer to Table 41-9.	Infusing too much IV solution results in an increase of circulating fluid volume.
a. Fluid overload can result in signs of cardiac and/or respiratory failure. Monitor intake and output and vital signs. Assess for edema and auscultate lung sounds. Ask if the patient is experiencing any shortness of breath.	Older adults are most at risk for this complication due to possible decrease in cardiac and/or renal functions.
b. Check for bleeding at the site.	Bleeding may be caused by anticoagulant medication. Bleeding at the site is most likely to occur when the IV is discontinued.
14. If appropriate, instruct the patient to call for assistance if any discomfort is noted at the site, the solution container is nearly empty, the flow has changed in any way, or if the electronic pump alarm sounds.	This facilitates patient engagement and safe administration of IV solution.
15. Remove PPE, if used. Perform hand hygiene.	Proper removal of PPE reduces the risk for infection transmission and contamination of other items. Hand hygiene prevents transmission of microorganisms.

DOCUMENTATION

Guidelines

Document the type of IV solution as well as the infusion rate. Note the insertion site location and site assessment.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Document the patient's reaction to the IV therapy as well as the absence of subjective reports that they are not experiencing any pain or other discomfort, such as coolness or heat associated with the infusion. In addition, record that the patient is not demonstrating any other IV complications, such as signs or symptoms of fluid overload. Document pertinent patient teaching. Document the IV fluid solution on the intake and output record.

Sample Documentation

11/6/25 1020 IV site right forearm/cephalic vein intact without swelling, redness, or drainage; dressing and stabilization device intact. D_5 0.9% NS with 20 mEq KCl continues to infuse at 110 mL/hr. Patient and partner instructed to call nurse with any swelling, discomfort or pain and verbalize an understanding of instructions.

—S. Barnes, RN

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

UNEXPECTED SITUATIONS AND ASSOCIATED INTERVENTIONS

- *Patient's lung sounds were previously clear, but now some crackles in the bases are auscultated, and the patient reports some shortness of breath:* Notify the health care team immediately. The patient may be exhibiting signs of fluid overload. Be prepared to tell the health care provider what the past intake and output totals were as well as the patient's vital signs and pulse oximetry assessment findings.
- *IV is not flowing as easily as it previously had been:* Check all clamps on the tubing, and check the tubing for any kinking. Check that the patient is not lying on the tubing. If the IV is over a joint, reposition the extremity and see if this helps the flow. Attempt to flush the PIVC with normal saline. If the IV is painful, you meet resistance when attempting to flush, or fluid still does not flow easily, discontinue the IV and restart it in another place.

EVOLVING CASE STUDY 41-1

Scenario: Jack Soo Park, a 78-year-old adult with a history of renal failure, is being treated for urosepsis. When Mr. Park was admitted 24 hours ago, he was disoriented, febrile, and had not been eating or drinking for several days as a result of "not feeling well" and is receiving intravenous fluid replacement and intravenous antibiotics. You have just finished receiving report and answer the patient's call bell. Mr. Park tells you, "I'm having trouble breathing."

QUESTION r/t CUES: Based on the patient's current situation, what assessment information is most important for the nurse to collect first?

A. Observe for edema in the lower extremities.
B. Review the complete metabolic panel results from earlier in the day.
C. Review the patient's baseline and current weight.
D. Assess the patient's lung sounds and oxygen saturation.

Scenario: While you are conducting your assessment, Mr. Park shares that he didn't sleep "at all" last night. Your assessment reveals the patient is very thin with a bounding pulse of 118, BP 142/90, crackles and wheezes in their lungs, and an oxygen saturation of 92%. You note that Mr. Park has a peripheral intravenous access device in his right forearm.

QUESTION r/t ANALYZING CUES: What other information (assessment data or evidence) should the nurse obtain to aid in determining the plan of care? Select all that apply.

A. Intake and output measurements
B. IV infusion site assessment
C. IV infusion solution and rate
D. The patient's usual sleep routine
E. 24-hour recall of dietary intake

Scenario: Mr. Park's intravenous infusion was prescribed to infuse at 125 mL/hr for the first 8 hours after admission and then be decreased to 40 mL/hr. A fluid-administration error resulted in the rate not being adjusted and your assessment reveals that the intravenous infusion has a current rate of 125 mL/hr.

QUESTION r/t PRIORITIZING HYPOTHESIS: Based on the assessment data for this patient, which ***priority*** patient problem should the nurse identify to guide the plan of care?

A. Impaired sleep
B. Fluid imbalance

C. Impaired nutritional intake
D. Fatigue

Scenario: After collaborating with the interprofessional team, you convert the intravenous to a capped peripheral venous access device and prepare to administer the prescribed 20-mg furosemide IV bolus.

QUESTION r/t GENERATING SOLUTIONS: Which action should be taken to evaluate or verify the integrity of the peripheral IV access site?

A. Remove the securement device to assess the site.
B. Document a negative aspiration for a blood return
C. Rotate the site every 72 hours.
D. Assess the skin temperature and tone at the site.

Scenario: Mr. Park's breathing has improved; he denies shortness of breath, dyspnea and pain, and his vital signs and oxygen saturation values are within expected limits. During one of your conversations, Mr. Park shares that "I don't always take my medications the way I'm supposed to. And, to tell the truth, I try not to drink a lot of liquids. I don't like to have to rush to the bathroom all the time!" After speaking with Mr. Park, you identify that problems with fluid balance occur at home as well. You and the patient agree there is a need for review and reinforcement of self-management strategies related to fluid balance.

QUESTION r/t TAKING ACTION: A second patient problem of deficient knowledge is identified. The nurse is preparing teaching materials for the patient. Which interventions should the nurse focus on with this patient? Select all that apply.

A. Monitoring of fluid intake and output.
B. Measuring weight at the same time each day.
C. Taking prescribed diuretics early in the day.
D. Keeping track of changes in breathing, weight, and urinary output to report at his 6-week check-up.
E. Restricting fluid intake to as little volume as possible.

Scenario: Mr. Park has been afebrile, and his vital signs and laboratory values have remained within expected parameters. His antibiotics have been changed to oral medications. Mr. Park is scheduled to be discharged home.

QUESTION r/t EVALUATING OUTCOMES: Based on the identified health problem, how will the nurse and Mr. Park *best* know that the plan of care has been effective?

A. The patient reports getting sufficient sleep at night.
B. The patient reports he is not experiencing dyspnea and his weight has remained stable.
C. The patient shares that he plans to take his diuretic every other day to avoid problems.
D. The patient's weight steadily increases over the next several weeks.

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

. Work through the Concept Map for on page 1714 and the Evolving Case Study 41-1 for Jack Soo Park on page 1728 to help develop your clinical reasoning and clinical judgment skills.
. Assess a healthy person and a patient whose fluid and electrolyte or acid–base balance is altered using Tables 40-3 and 40-4, which describe parameters to be considered in physical and clinical assessments for fluid, electrolyte, and acid–base balance. Compare and contrast your findings.
. Review the record of a patient who has been receiving IV fluids over a period of 3 or more days. Note the daily intake and output records, pertinent laboratory values, and clinical behaviors, and make a judgment about the patient's fluid, electrolyte, and acid–base balance. What factors complicate a hospitalized patient's usual ability to remain in balance?

PRACTICING FOR NCLEX

. A nurse on the respiratory unit is interpreting ABGs for several patients. The patient with which problem will the nurse suspect may have developed respiratory alkalosis?

a. Hypoxia
b. Atelectasis
c. Chronic respiratory illness
d. Sedative overdose

. A nurse is caring for a group of patients. The patient with which problem would the nurse identify is at high risk for fluid volume excess?

a. Renal failure

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

b. Vomiting
c. Hypernatremia
d. NPO for surgery

. A nurse is caring for a patient who has developed hypernatremia. For which intravenous solution would the nurse anticipate a prescription?
a. 5% dextrose in 0.9% NaCl
b. 0.9% NaCl (normal saline)
c. 0.45% NaCl (½-strength normal saline)
d. 5% dextrose in lactated Ringer's solution

. A nurse is assessing infants in the NICU for fluid balance status. Which nursing action would the nurse depend on as the most reliable indicator of a patient's fluid balance status?
a. Recording intake and output
b. Testing skin turgor
c. Reviewing the complete blood count
d. Measuring weight daily

. A nurse is caring for a patient in the intensive care unit. How will the nurse interpret the patient's arterial blood gas values: pH, 7.30; $PaCO_2$, 36 mm Hg; HCO_3^-, 14 mEq/L?
a. Respiratory acidosis
b. Respiratory alkalosis
c. Metabolic acidosis
d. Metabolic alkalosis

. A patient with dehydration has been encouraged to increase fluid intake. Which measure would be most effective for the nurse to implement?
a. Explaining the mechanisms of fluid transport in cellular compartments
b. Keeping the patient's preferred fluids readily available for the patient
c. Emphasizing the long-term benefit of increasing fluids
d. Planning to offer most daily fluids in the evening

. A nurse is flushing a patient's peripheral venous access device. The nurse finds that the access site is leaking fluid during flushing. What action will the nurse take next?
a. Removing the IV from the site and start at another location
b. Immediately notifying the primary care provider
c. Outlining the affected area in ink and monitoring for changes
d. Aspirating the catheter and attempting to flush again

. A nurse is monitoring a patient who is receiving an IV infusion of normal saline at 250 mL /hr. The patient is apprehensive and presents with a pounding headache, rapid pulse, chills, and dyspnea. What would be the nurse's priority intervention related to these symptoms?
a. Discontinuing the infusion immediately, monitoring vital signs, and reporting findings to the primary care provider immediately
b. Slowing the rate of infusion, notifying the primary care provider immediately, and monitoring vital signs
c. Pinching off the catheter or securing the system to prevent entry of air, placing the patient in the Trendelenburg position, and calling for assistance
d. Discontinuing the infusion immediately, applying warm compresses to the site, and restarting the IV at another site

. A nurse carefully assesses the acid–base balance of a patient whose bicarbonate (HCO_3^-) level is decreased on the ABG results. This typically occurs in patients with damage to which organ?
a. Kidneys
b. Lungs
c. Adrenal glands
d. Brain

. A nurse is monitoring a patient who is diagnosed with hypokalemia. Which nursing intervention would be appropriate for this patient?
a. Encouraging foods and fluids with higher sodium content
b. Administering oral potassium supplements as prescribed
c. Cautioning the patient about eating foods high in potassium content

d. Discussing calcium-losing aspects of nicotine and alcohol use

. A nurse has begun administering an intravenous antibiotic via the patient's peripheral venous access. Immediately, the nurse observes that the fluid does not flow easily into the vein and the skin around the insertion site is edematous and cool to the touch. What would be the nurse's next action related to these findings?

a. Repositioning the extremity and raise the height of the IV pole
b. Applying pressure to the dressing on the IV
c. Pulling the catheter out slightly and reinserting it
d. Putting on gloves; removing the catheter

. When caring for a patient receiving hemodialysis through an arteriovenous fistula, which action is essential for the nurse to take?

a. Avoiding IM injections
b. Not assessing the radial pulse on the same side as the access
c. Performing BP and venipuncture on the opposite extremity
d. Using the distended portion of the fistula for IV medications

. A nurse is administering a blood transfusion for a patient following surgery. During the transfusion, the patient displays signs of dyspnea, dry cough, and pulmonary edema. What would be the nurse's priority actions related to these symptoms?

a. Slowing or stopping the infusion; monitoring vital signs, notifying the health care provider, and placing the patient in an upright position with their feet dependent
b. Stopping the transfusion immediately and keeping the vein open with normal saline, notifying the health care provider immediately, and administering antihistamine parenterally as needed
c. Stopping the transfusion immediately and keeping the vein open with normal saline, notifying the health care provider, and treating symptoms with acetaminophen
d. Stopping the infusion immediately, obtaining a culture of the patient's blood, monitoring vital signs, notifying the health care provider, and administering antibiotics immediately

. A nurse is performing physical assessments for patients with fluid imbalance. Which findings indicate a fluid volume excess? Select all that apply.

a. Pinched and drawn facial expression
b. Deep, rapid respirations
c. Moist crackles heard upon auscultation
d. Tachycardia
e. Distended neck veins
f. Sluggish skin turgor

. A nurse is caring for a patient experiencing a fluid volume deficit. What should be included in the recorded intake and output for the patient? Select all that apply.

a. Urine
b. Carbonated beverage
c. Formed stool
d. Vomitus
e. Chicken noodle soup
f. Pressure wound irrigant

. A nurse is caring for an older adult with a fluid volume deficit related to decreased thirst sensation. For which signs and symptoms of this health problem will the nurse assess?

a. Dependent edema
b. Crackles in the lungs
c. Neck vein distention
d. Weight loss

. A nurse on the IV team is making rounds to assess patients receiving IV therapy. Under which circumstance will the nurse recommend an intravenous catheter be discontinued?

a. The area surrounding the catheter is bruised.
b. The patient's extremity is cool to touch.
c. The site is red, warm, and swollen.
d. Part of the catheter (1 mm) is visible under the dressing.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

ANSWERS WITH RATIONALES

. **a.** Patients experiencing hypoxia will breathe rapidly, "blowing off" CO_2. This drives the pH up reflecting alkalosis related to the respiratory system.

. **a.** Patients with renal (kidney) failure are unable to excrete fluids; they typically have oliguria and fluid volume excess. The other patient scenarios typically occur in patients with fluid volume deficit.

. **c.** A solution of 0.45% NaCl (½-strength normal saline) or 0.33% NaCl (⅓-strength normal saline) are hypotonic fluids used to treat hypernatremia. As there are less particles in the ½-strength saline than in the bloodstream, infusing this fluid will cause the sodium level to decrease. Normal saline (0.9% NaCl) is used to treat hypovolemia, metabolic alkalosis, hyponatremia, and hypochloremia. Lactated Ringer's solution is used in the treatment of hypovolemia, burns, and fluid lost from gastrointestinal sources. Dextrose (5%) in lactated Ringer's solution replaces electrolytes and shifts fluid from the intracellular compartment into the intravascular space, expanding vascular volume.

. **d.** Daily weight is the most reliable indicator of fluid balance. Intake and output are not always as accurate and may involve a subjective component. Testing skin turgor may not be totally accurate due to loose skin; measurement of skin turgor is subjective. The complete blood count itself does not necessarily reflect fluid balance; however, a high hematocrit can provide further support for fluid excess or deficit.

. **c.** The first step is to analyze the pH; low pH indicates acidosis. This, coupled with a low bicarbonate (regulated by the kidney), indicates metabolic acidosis. The pCO_2 is normal, indicating the acid–base disturbance is nonrespiratory in origin. The pH and bicarbonate would be elevated with metabolic alkalosis. Decreased $PaCO_2$ in conjunction with a low pH indicates respiratory acidosis; increased $PaCO_2$ in conjunction with an elevated pH indicates respiratory alkalosis.

. **b.** Having fluids the patient prefers readily available and within reach helps promote intake. Explanation of the fluid transport mechanisms is inappropriately complex and does not address dehydration. Meeting short-term outcomes rather than long-term outcomes is the priority at this time provides further reinforcement, and additional fluids should be taken earlier in the day.

. **a.** If the peripheral venous access site leaks fluid when flushed, the nurse should remove it from the site; evaluate the need for continued access; and, if clinically necessary, restart the IV in another location. This action is a nursing intervention; the primary care provider does not need to be notified first. The nurse should use a skin marker to outline the area with visible signs of infiltration to allow for assessment of changes or aspirate and attempt to flush again if the IV does not flush easily.

. **a.** The nurse is observing the signs and symptoms of speed shock: the body's reaction to a substance that is injected into the circulatory system too rapidly. The nursing interventions for this condition are discontinue the infusion immediately, report symptoms of speed shock to primary care provider immediately, and monitor vital signs once signs develop. The other choices are interventions for fluid overload; air embolus; and phlebitis, respectively.

. **b.** The kidney primarily controls the bicarbonate level and, if damaged, can affect acid–base balance. The adrenal glands secrete catecholamines and steroid hormones. The brain may regulate respiration and therefore CO_2, not the bicarbonate level.

. **b.** Nursing interventions for a patient with hypokalemia include encouraging foods high in potassium and administering (oral) potassium supplements as prescribed. Encouraging foods with high sodium content is appropriate for a patient with hyponatremia. Cautioning the patient about foods high in potassium is appropriate for a patient with hyperkalemia and discussing the calcium-losing aspects of nicotine and alcohol use is appropriate for a patient with hypocalcemia.

. **d.** The IV fluid is infiltrating the tissue, suggested by lack of flow, swelling, and the area feeling cool to the touch. The nurse should put on gloves and remove the catheter. The nurse should also use a skin marker to outline the area with visible signs of infiltration to allow for assessment of changes and secure gauze with tape over the insertion site without applying pressure. The nurse should assess the area distal to the venous access device for capillary refill, sensation and motor function and restart the IV in a new location. Finally, the nurse should estimate the volume of fluid that escaped into the tissue based on the rate of infusion and length of time since last assessment, notify the primary health care provider and use an appropriate method for clinical management of the infiltrate site, based on infused solution and facility guidelines, and record site assessment and interventions, as well as site for new venous access. Raising the height of the IV pole will increase the pressure causing fluid to flows; however, that will promote further infiltration of fluid.

. **c.** When caring for a patient with an arteriovenous fistula for dialysis, it is essential the nurse does not compress the area. Therefore, no BP or venipuncture is performed in that extremity. The patient may receive IM injections in an area of the body without the access. Taking a radial pulse in the arm with the access will not harm the fistula. The nurse does not use the fistula for any reason other than dialysis; damage to the fistula delays lifesaving dialysis.

. **a.** The patient is displaying signs and symptoms of circulatory overload: too much fluid volume as a result of the infusion of blood. In the other choices, the nurse is providing interventions for an allergic reaction; responding to a

febrile reaction; and providing interventions for a bacterial reaction, respectively.

- **c, d, e.** Moist crackles, neck vein distention, and tachypnea typically indicate fluid volume excess. A person with a severe fluid volume deficit may have a pinched and drawn facial expression. Deep, rapid respirations may be a compensatory mechanism for metabolic acidosis or a primary disorder causing respiratory alkalosis. Tachycardia is usually the earliest sign of the decreased vascular volume associated with fluid volume deficit. Sluggish skin turgor is present with fluid volume deficit.
- **a, b, d, e.** The nurse includes urine, emesis, liquid stool, drainage from wounds, and drains in the output. Intake includes IV fluids, foods, and liquid at room temperature. The liquid portion of the chicken noodle soup can be measured; however, the nurse excludes the solids. Irrigation to a pressure wound is not absorbed; rather, it drains out after cleansing the wound.
- **d.** Assessing weight is the most sensitive indicator of fluid balance. As fluid is lost, the patient's weight will decrease. The other options are indicative of fluid excess.
- **c.** The IV nurse will assess the IV fluids, rate, and site. A site that is red, warm, and swollen may have developed phlebitis, and the IV catheter should be removed. A bruised area surrounding the insertion site is likely associated with the initial insertion and can be monitored. A patient with a cool extremity may be chilly or hypothermic; the nurse assesses the IV site. Having 1 mm of the catheter visible from the insertion site that is covered with an occlusive, transparent dressing does not require immediate action.

UNIT VII Promoting Healthy Psychosocial Responses

Every person is a composite of interrelated physiologic, psychosocial, and spiritual dimensions; alterations in one dimension affect the others. Unit VII discusses psychosocial considerations in holistic, person-centered care, focusing on sense of self; stress and adaptation; loss, grief, and dying; sensory stimulation; sexuality; and spirituality.

Each person's sense of self is critical to that person's attitudes toward health and may affect self-care abilities positively or negatively. Additionally, developmental or experiential stressors can motivate or thwart psychosocial growth and self-actualization. Nursing interventions to promote healthy psychosocial responses—including maintaining, strengthening, or changing self-concept—are basic to all aspects of patient care. Because a person's sense of self shapes their ability to respond to health care interventions, nurses include assessment and intervention to promote a positive sense of self.

Loss, grief, and dying are universal human experiences that most nurses encounter in some form on a daily basis. Effective nurses are competent and willing to assist people struggling with loss, grief, and dying.

Intact, functioning senses are necessary for life, normal growth and development, communication, and pleasurable experiences. Alterations in any of the senses require caring, knowledgeable, and individualized nursing interventions to meet needs, enhance individual independence, and prevent further overload or deprivation.

Sexuality and spirituality are also important components of human functioning. These dimensions are an integral part of each person's identity and are critical elements in holistic patient care. Nurses recognize the importance of these areas for optimal health and use their knowledge and skills to assist patients to enhanced wellness in these areas.

To facilitate wellness in each of these psychosocial spheres, nurses must develop self-awareness, including knowledge of their own personal attitudes, values, perceptions, and practices, as well as understand how others differ in these characteristics. Nurses' own personal biases, including the ability to accept others who have cultural, spiritual, racial, ethnic, or sexual identity characteristics that differ from their own, affect their ability to plan and provide optimal care. Nursing interventions and therapeutic interpersonal skills are used to elicit concerns, identify needs, implement teaching, make referrals, and demonstrate empathic caring and acceptance.

"The unique function of the nurse is to assist the individual … in the performance of those activities contributing to health or its recovery (or to peaceful death) that he would perform unaided if he had the necessary strength, will or knowledge … in such a way as to help him gain independence as rapidly as possible."

Virginia Henderson (1897-1996), *the "first lady of nursing," whose career spanned almost 70 years as both author and researcher; her works on nursing principles are research based and have been translated into 25 languages*

Self-Concept

Anthony Santorini

Anthony is a 44-year-old male with a history of diabetes. He recently underwent a below-the-knee amputation because of complications resulting from poor glucose control. One morning, he states, “I feel like damaged goods. I’m not a whole man anymore.”

Melissa Motsky

Melissa is a 31-year-old married mother of three children ages 12, 10, and 8. She is a third-year nursing student in academic jeopardy. Melissa cries and calls herself a failure when speaking to an academic advisor, seeing no way to get out of her current predicament.

Delores Sparks

Delores is a 72-year-old widow diagnosed with advanced lung cancer 14 months ago. She had been living alone in a small apartment until 9 months ago, when she moved in with her daughter after a lengthy hospital stay because she was no longer capable of living alone. Delores has a probable prognosis of 3 months to live at most. A recent home visit reveals that the patient is increasingly depressed and feels like a burden to her daughter. She states, “I’m just an old dish rag, not good for

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

anything anymore."

Learning Outcomes

After completing the chapter, you will be able to accomplish the following:

. Describe three dimensions of self-concept: self-knowledge, self-expectations, and self-evaluation (self-esteem).
. Identify major steps in the development of self-concept.
. Differentiate positive and negative self-concept and high and low self-esteem.
. Identify six variables that influence self-concept.
. Use appropriate interview questions and observations to assess a patient's self-concept.
. Describe how the experience of aging, illness, trauma, disability, loss, diagnostic testing, and treatment can threaten a patient's self-concept.
. Develop nursing diagnoses/health problems to identify disturbances in self-concept (body image, self-esteem, role performance, personal identity).
. Describe nursing strategies that are effective in resolving self-concept problems.
. Plan, implement, and evaluate nursing care related to select diagnoses/health problems for disturbances in self-concept.

self-concept
self-esteem

Self-concept, or self-image, is crucial to a person's health and well-being throughout life. A person's **self-concept**, which is the mental image or picture of self, has the power to either encourage or thwart personal growth. People with deficient self-concept may lack the motivation to learn self-care behaviors in response to illness, injury, or trauma. Nursing efforts aimed at teaching new health behaviors may fail until the patient values themselves enough to want to invest energy in self-care. Some patients may be aware that their negative self-concept affects their health behaviors, and may desperately want to make modifications, but have no idea how to do so. In addition, the experience of aging, illness, disability, trauma, loss, diagnostic testing, and treatment can severely threaten a patient's self-concept. Nurses who are sensitive to patients' expressions of self-concept can use each nurse–patient interaction to enhance a patient's sense of self and to assist the patient in resolving self-concept disturbances (see the Reflective Practice box on page 1738 for an example).

Several variables contribute to self-concept. As discussed in Chapter 4, as people move through the hierarchy of human needs to higher levels, needs for self-esteem and self-actualization arise. The need for **self-esteem** is the need that people have to feel good about themselves and to believe that others hold them in high regard. The need for **self-actualization** is the need for people to reach their full potential through development of their unique capabilities. Disturbances in self-concept may occur for a number of reasons. **Identity diffusion** is the failure to integrate various childhood identifications into a harmonious adult psychosocial identity, which can lead to disruptions in relationships and problems of intimacy. **Depersonalization** is a person's subjective experience of the partial or total disruption of the

ego and the disintegration and disorganization of self-concept (Stuart, 2013). Figure 42-1 illustrates the continuum of self-concept responses.

OVERVIEW OF SELF-CONCEPT

Dimensions of Self-Concept

All of the feelings, beliefs, and values associated with "I" or "me" compose self-concept. Specific components of self-concept include personal identity, body image, self-esteem, and role performance. Crucial to each component are the dimensions of self-concept, which include self-knowledge, self-expectations, and self-evaluation.

People with a positive self-concept usually have greater and more diversified self-knowledge, more realistic perceptions and expectations, and a higher evaluation of themselves or higher self-esteem, whereas those with negative self-concept tend to exhibit poorer self-knowledge, less realistic perceptions and expectations, and lower self-esteem.

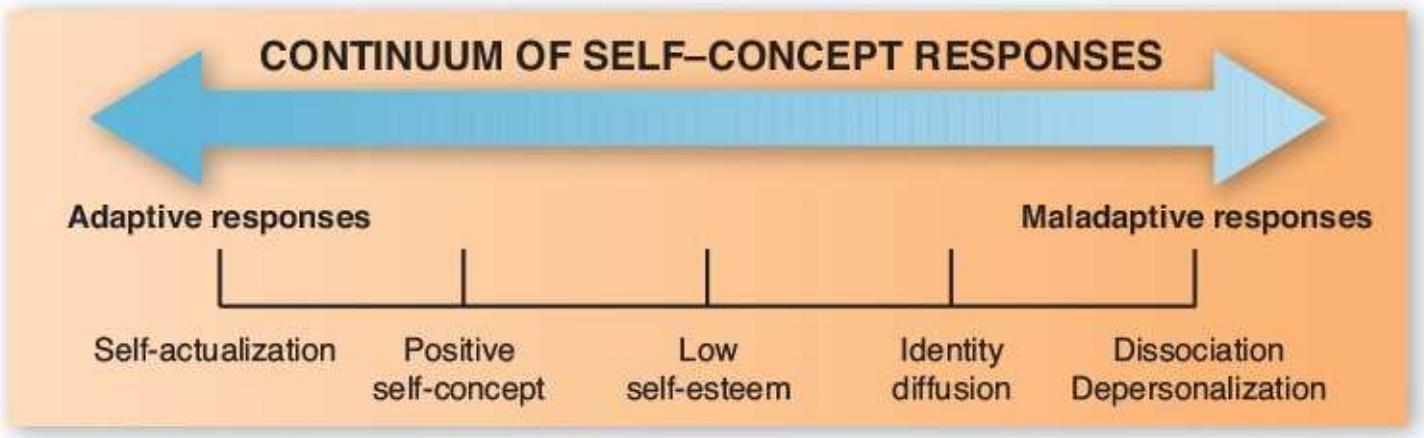

FIGURE 42-1. Continuum of self-concept responses. (*Source:* Reprinted with permission from Stuart, G. W. [2013]. Principles and practice of psychiatric nursing [10th ed., p. 264]. Elsevier/Mosby.)

QSEN Reflective Practice: Cultivating QSEN Competencies

CHALLENGE TO INTERPERSONAL SKILLS

Mrs. Delores Sparks is a 72-year-old, widowed, African American female. Before her diagnosis of advanced lung cancer 14 months ago, she lived alone in a small apartment. Nine months ago, following a lengthy hospital stay, she moved in with her daughter when it was determined that she was no longer capable of living alone and probably had, at most, 3 months to live. I was visiting her during my home health care nursing experience and growing more and more concerned with her depression. Mrs. Sparks verbalized that she felt like a burden to her daughter, who has three children herself and was currently taking care of a granddaughter as well. Mrs. Sparks was being treated for her depression, but I was concerned about the effects all this was having on her self-concept. She told me she was like "an old dish rag" that wasn't good for anything anymore.

Thinking Outside the Box: Possible Courses of Action

- Try to cheer her up at each visit.
- Ignore her deteriorating self-concept, since focusing on it may only make her feel worse; it is certainly true that she has enough bad stuff going on in her life to make her feel bad.
- Explore sources of positive affirmations of her worth; try to use my professional relationship with her to communicate "You are a person of worth and I care about you!"

Evaluating a Good Outcome: How Do I Define Success?

- Mrs. Sparks' self-concept improves.
- I learn how to communicate a sense of worth to vulnerable patients.
- I learn how to address problems with self-concept.

Personal Learning: Here's to the Future!

Unfortunately, this situation got worse before it got better. Mrs. Sparks did not always take her meds for depression, and her daughter voiced increasing frustration with her mother's mood. "Mom talks all the time now about how even God doesn't want her. She says that she may have to take her own life since God doesn't seem to be doing it!" The daughter also said that Mrs. Sparks apologized to her constantly for being such a bother. Things didn't start to change until I learned that Mrs. Sparks used to be a very

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

important member of her church community. She stopped attending services when she got too weak to go out. This was clearly a major loss for her. When I successfully got her minister to visit, he literally turned her life around, providing her with lots of positive reinforcement for how she could use her illness to do God's work. She seems much more peaceful now. I've also encouraged her to tell me stories about the church work she did in the past and these reminiscences seem to be helpful.

QSEN SELF-REFLECTION ON QUALITY AND SAFETY COMPETENCIES DEVELOPING KNOWLEDGE, SKILLS, AND ATTITUDES FOR CONTINUOUS IMPROVEMENT

Do you agree with the criteria that the nursing student used to evaluate a successful outcome? Why or why not? What *knowledge, skills,* and *attitudes* do you need to develop to continuously improve the quality and safety of care for patients like Mrs. Sparks?

Patient-Centered Care: How would you develop a respectful and successful partnership with Mrs. Sparks and her daughter? How might your interpersonal skills influence her self-concept?

Teamwork and Collaboration/Quality Improvement: What special competence did the minister bring to Mrs. Sparks? What other members of your caregiving team can you consult? What does quality care for this family "look like"?

Safety/Evidence-Based Practice: Describe the patient's self-concept in the dimensions of self-knowledge, self-expectations, and self-evaluation. What does the evidence point to as "best practice" for Mrs. Sparks? What safety needs does she have, and how can you meet them?

Informatics: Can you identify the essential information that must be available in Mrs. Spark's electronic record to support safe patient care and coordination of care? Can you think of other ways to respond to or approach the situation? What else might the nursing student have done to ensure a successful outcome?

Consider Anthony Santorini, the patient with a below-the-knee amputation. Analysis of this patient's comments would indicate that he is experiencing a negative self-concept. The nurse would need to assess Mr. Santorini more closely to determine their self-knowledge, self-expectations, and self-evaluation for each component of self-concept. This would help the nurse identify possible factors contributing to their status and gain a fuller picture of Mr. Santorini's current condition.

Self-Knowledge: "Who am I?"

Global self is the term used to describe the composite of all the basic facts, qualities, traits, images, and feelings people hold about themselves. These factors strongly influence a person's ability to manage life events and ensure emotional stability. A person's self-knowledge includes:

- basic facts (sex assigned at birth, age, ethnicity, occupation, cultural background, sexual orientation);
- the person's position within social groups; and
- qualities or traits that describe typical behaviors, feelings, moods, and other characteristics (e.g., generous, hotheaded, ambitious, intelligent).

Although some labels cannot be changed (e.g., age and ethnicity), most are subjective and sensitive to change. Some conditions associated with alterations in self-concept or global self-worth include developmental changes, life crisis, illness, disability, and loss.

Think back to **Delores Sparks**, the older woman with advanced lung cancer who feels like a burden. When assessing her global self-worth, the nurse would need to identify any developmental changes Mrs. Sparks is experiencing that may be contributing to her current status, such as changes related to her increasing age. In addition, information about role changes, including the inability to care for herself and the need to be dependent owing to her illness, in conjunction with the knowledge of her terminal condition and anticipatory grieving related to her death, would be essential for determining her feelings of global self-worth.

Self-Expectations: "Who or What Do I Want to Be?"

Expectations for the self flow from various sources. The **ideal self** constitutes the self one wants to be. These self-expectations develop unconsciously early in childhood and are based on images of role models such as parents, other caregiving figures, and public figures. These personal expectations may be healthy or unhealthy. Contrast the significance of a child's identifying a television "bad boy" or a drug dealer as their hero rather than parents, civic leaders, or other professional people. A **false self** may develop in people who have an emotional need to respond to the needs and ambitions significant people, such as parents, have for them.

Self-Evaluation: "How Well Do I Like Myself?"

Self-esteem is the evaluative and affective component of the self-concept, sometimes termed *self-respect, self-approval,* or *self-worth.* According to Maslow (1954, p. 90), all people "have a need or desire for a stable, firmly based, usually high evaluation of themselves, for self-respect or self-esteem, and for the esteem of others." Accordingly, he identified two subsets of esteem needs: (1) self-esteem needs, such as strength, achievement, mastery and competence, confidence in the face of the world, independence, and freedom; and (2) respect needs or the need for esteem from others, such as status, dominance, recognition, attention, importance, and appreciation. For Maslow, self-esteem comes from two major sources: how competent children think they are in various aspects of life and how much social support they receive from other people. A person's self-esteem, like the various self-images that make up a person's self-concept, varies considerably in relation to specific relationships or situations.

Coopersmith (1967) identified the four bases of self-esteem as (1) *significance*, or the way people feel they are loved and approved of by the people important to them; (2) *competence*, or the way tasks that are considered important are performed; (3) *virtue*, or the attainment of moral–ethical standards; and (4) *power*, the extent to which people influence their own and others' lives. According to Coopersmith, people with high, medium, and low self-esteem differ in their expectations of the future, in their affective reactions, and in their basic styles of adapting to environmental demands. People with high self-esteem, for example, are accustomed to being well received and successful. They are able to approach people, tasks, and new situations freely, with confidence in their ability to interact and to get along with people and to respond successfully to life's challenges. With healthy self-esteem, you are:

- Assertive in expressing your needs and opinions
- Confident in your ability to make decisions
- Able to form secure and honest relationships—and less likely to stay in unhealthy ones
- Realistic in your expectations and less likely to be overcritical of yourself and others
- More resilient and better able to weather stress and setbacks (Mayo Clinic, 2020a)

Three major self-evaluation feelings or affects found in people are (1) *pride*, based on a positive self-evaluation, (2) *guilt*, based on behaviors incongruent with ideal self, and (3) *shame*, associated with low global self-worth. These affects are learned in early childhood within relationships with significant others and maintained through practice.

Sullivan (1953) proposed the self-representations of "good-me" and "bad-me" based on reflected appraisals of the self, learned in the context of a child's early relationship with significant others, especially parents. The child's feelings of self-esteem and self-worth develop out of that child's perceptions of the parenting figure's feelings, or affects, expressed in caring for the child. Sullivan posited that children perceived their parents' relative anxiety through a process he termed "empathy." Children exposed to higher levels of parental anxiety are at risk for developing lower self-esteem and a greater self-representation of "bad-me." As the child developed further, that child would begin to behave in ways that confirmed the earlier self-appraisals.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Sullivan and their most important interpreter within nursing, Hildegard Peplau (1952, 1997), emphasized the fluidity of self-appraisals throughout the life span. They taught that positive interaction at any point in a person's life with new significant others (such as nurses) who are less anxious and more accepting and nurturing than prior figures can have a positive, growth-promoting effect on that person's self-esteem and self-concept.

Bowlby (1969) developed attachment theory, which describes modes by which a young child develops and maintains feelings about the self as well as values and beliefs about the world. Attachment is a process by which the child maintains felt security via an interpersonal bond with close caregivers, most notably parents. Through a learning process based on children's perception of their caregivers' thoughts and reactions toward them, children form a sense of self as secure or insecure, calm or anxious, likable or not. Through this process, a child also develops beliefs and feelings about others as well as individual perceptions of situations and events. The growing child's self-esteem is affected by how healthy the child's attachment experience is with the early caregiver. If the attachment is secure, the child's thoughts and feelings about events are likely to closely match reality; if the attachment is insecure, the child's thoughts and feelings about events may be distorted and out of touch with reality. Such patterns tend to remain relatively fixed into adulthood.

Formation of Self-Concept

Although self-concept is largely considered to be a social creation that develops as a result of interactions with others (Fig. 42-2), contemporary nursing researchers and others recognize that certain inborn tendencies, such as temperament, when interacting with social and interpersonal experiences, are crucial in the formation of self-concept. Psychoanalysts have also emphasized the importance of inborn traits, such as innate aggression, because they affect a child's interpersonal experiences and shape self-concept (Freud, 1961). According to the theoretical formulations previously stated, the formation of self-concept includes the following:

FIGURE 42-2. Interaction between caregiver and infant, such as feeding, holding, cuddling, and cooing, are important to the child's development.

. An infant learns that the physical self is different from the environment. If basic needs are met, warmth and affection are experienced, and the caregivers' anxiety is minimized, then the child begins life with positive feelings about self.
. The child next internalizes (incorporates into self) other people's attitudes toward self, including attitudes directed toward the child's innate tendencies, such as temperament and aggression. This internalization forms the foundation of self-concept. Parents or other direct caregivers play the most influential role; peers play the second most influential role. Later, the child continues to behave in ways that confirm this early self-concept. How loved you felt as a child is a great predictor of how you manage all sorts of difficult situations later in life (Zimmeran, 2020).
. The child or adult internalizes the standards of society.

Stages in the development of the self include self-awareness (infancy), self-recognition (18 months), self-definition (3 years), and self-concept (6 to 7 years). Psychological conditions that foster healthy development of the self in children include:

- Emotional warmth and acceptance
- Effective structure and discipline
- Clearly defined standards and limits, so that children understand what goals, procedures, and conduct are approved
- Adequately defined roles for both older and younger members of the family
- Established methods of handling children that produce the desired behavior, discourage misbehavior, and deal with infractions when they occur
- Encouragement of competence and self-confidence (Fig. 42-3)

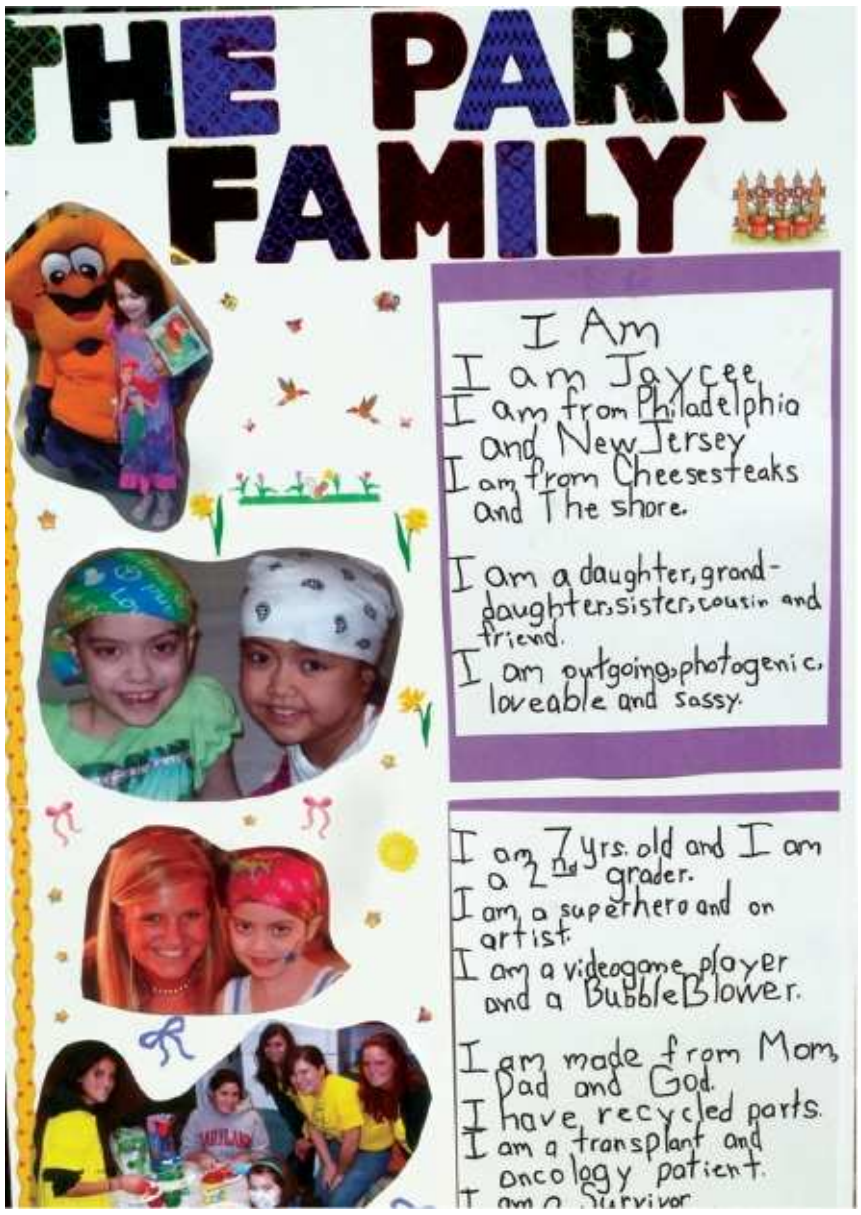

FIGURE 42-3. Jaycee's artwork illustrates a healthy self-concept. (Used with permission.)

- Helping children meet challenges
- Appropriate role models
- Stimulating and responsive environment

Formation of self-concept is further described in developmental theories, especially in Erikson's stages of development, Piaget's cognitive developmental stages, and Havighurst's developmental tasks (see Chapters 22 and 23).

Preventing Adverse Child Experiences

According to the Centers for Disease Control and Prevention (CDC) adverse childhood experiences, or ACEs, are potentially traumatic events that occur in childhood (ages 0–17 years). For example:

- Experiencing violence, abuse, or neglect
- Witnessing violence in the home or community
- Having a family member attempt or die by suicide

Also included are aspects of the child's environment that can undermine their sense of safety, stability, and bonding such as growing up in a household with:

- Substance misuse
- Mental health problems
- Instability due to parental separation or household members being in jail or prison.

It is critically important for every nurse to understand that ACEs are linked to chronic health problems, mental illness, and substance misuse in adulthood. ACEs can also negatively impact education and job opportunities. See Box 42-1 for strategies to prevent ACEs, and check the CDC website to learn more about the consequences of ACEs (https://www.cdc.gov/violenceprevention/aces/fastfact.html?CDC_AA_refVal=https%3A%2F%2Fwww.cdc.gov%2Fviolenceprevention%2Facestudy%2Ffastfact.html).

Box 42-1 Preventing Adverse Childhood Experiences

ACEs are preventable. Creating and sustaining safe, stable, nurturing relationships and environments for all children and families can prevent ACEs and help all children reach their full potential. The CDC has produced a resource, Preventing Adverse Childhood Experiences (ACEs): Leveraging the Best Available Evidence (https://www.cdc.gov/violenceprevention/pdf/preventingACES.pdf), to help states and communities take advantage of the best available evidence to prevent ACEs. It features six strategies from

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

the CDC Technical Packages to Prevent Violence (https://www.cdc.gov/violenceprevention/communicationresources/pub/technical-packages.html).

Strategy	Approach
Strengthen economic supports to families	• Strengthening household financial security • Family-friendly work policies
Promote social norms that protect against violence and adversity	• Public education campaigns • Legislative approaches to reduce corporal punishment • Bystander approaches • Men and boys as allies in prevention
Ensure a strong start for children	• Early childhood home visitation • High-quality childcare • Preschool enrichment with family engagement
Teach skills	• Social–emotional learning • Safe dating and healthy relationship skill programs • Parenting skills and family relationship approaches
Connect youth to caring adults and activities	• Mentoring programs • After-school programs
Intervene to lessen immediate and long-term harms	• Enhanced primary care • Victim-centered services • Treatment to lessen the harms of ACEs
Raising awareness of ACEs can help: • Change how people think about the causes of ACEs and who could help prevent them. • Shift the focus from individual responsibility to community solutions. • Reduce stigma around seeking help with parenting challenges or for substance misuse, depression, or suicidal thoughts. • Promote safe, stable, nurturing relationships and environments where children live, learn, and play. Let's help all children reach their full potential and create neighborhoods, communities, and a world in which every child can thrive.

Factors Affecting Self-Concept

Almost any life experience can influence a person's self-concept. Key factors include developmental considerations, culture, internal and external resources, history of success and failure, stressors, and illness or trauma.

Developmental Considerations

As a person matures, the criteria that mark the experiences necessary for a positive self-concept change. Although the infant needs a supportive environment in which all human needs are met, the growing child needs the freedom to explore and develop the ability to meet increasing personal needs. Table 42-1 highlights developmental changes affecting self-concept, related implications for nursing, and potential causes of self-concept disturbances. Box 42-2 on page 1744 invites you to test your clinical reasoning and judgment. See also Chapters 22–24.

Culture

As a child internalizes the values of parents and peers, culture begins to influence a sense of self. If the culture is relatively stable, little tension may be experienced between what culture expects of the child and what the child expects of self. When parents, peers, and the adult world confront the child with different cultural expectations, however, the sense of self may become confused. For example, an adolescent might realize their parents live by the work ethic and believe it is necessary to rise early every day and put in a full day's work. That adolescent's peer group, however, has few demands placed on it and encourages the adolescent to hang out with the group. The adolescent's vocational aptitudes, meanwhile, are leading them to consider a music career in a rock group, which will keep the adolescent out late many nights doing something the parents do not classify as work.

Children of immigrants whose values and practices of their culture of origin vary from the culture of adoption face

cultural dissonance. Parents may expect children to behave according to their own cultural norms, whereas peers and society, as well as the adolescent's wish to "belong," may create the desire to abandon old cultural beliefs, attitudes, and practices. Conflict between parents and children, as well as cultural confusion, may occur.

Refer to the accompanying Research in Nursing box for a study concerning how acculturation into the nursing profession affected the self-esteem in nursing students.

Internal and External Resources

The personal strengths a person recognizes, develops, and uses are powerful but subjective determinants of self-concept. For example, one person may use humor as both an effective coping mechanism and a successful interpersonal tool. Another person may use humor to avoid facing conflict but may feel badly about being known as a "joker" or "clown." The degree to which a person integrates healthy, useful internal resources or personal strengths is associated with how well a person has been able to establish a positive self-concept in the context of nurturing experiences.

Research in Nursing

Bridging the Gap to Evidence-Based Practice

Nursing Students' Understanding of the Concept of Self-Esteem

Positive self-esteem helps students academically and facilitates development of the role of the professional nurse. That said, little study has been done on nursing students' self-esteem.

Related Research

Zamanzadeh, V., Valizadeh, L., Gargari, R. B., Ghahramanian, A., Tabriz, F. J., & Crowley, M. (2016). Nursing students' understanding of the concept of self-esteem: A qualitative study. *Journal of Caring Science*, *5*(1), 33–41.

This study aimed to discover the extent and characteristics of the concept of self-esteem from the perspective of Iranian nursing students through a qualitative approach. Purposive sampling was used to recruit participants and data were collected through in-depth semistructured interviews and analyzed simultaneously. The results revealed that from the nursing students' perspective, self-esteem referred to the value they gave to being a nursing student. From the findings, three main themes emerged and related to "enthusiasm about being a nursing student," "socialization into the profession," and "sense of worth related to perceived professionalism level."

Relevance to Nursing Practice

This study revealed that the nursing students' self-esteem is influenced greatly by their professionalization and socialization. Faculty should give more attention to the factors that facilitate the development of higher levels of self-esteem among nursing students during curriculum development. The study authors noted that the concept of self-esteem is affected by different cultural influences and contexts. This study was conducted in northwest Iran, and it would be helpful to replicate it in other countries.

Self-concept is also associated with the ability to identify and use external resources, such as a network of support people, adequate finances, and organizational supports. People who feel more positive about themselves tend to feel connected to others and to society; they can identify and use more external resources. People who feel disconnected and alone tend to perceive and use fewer environmental resources.

Table 42-1 Developmental Changes Affecting Self-Concept

DEVELOPMENTAL PERIOD	CHANGES AFFECTING SELF-CONCEPT	IMPLICATIONS FOR NURSING	POTENTIAL CAUSES OF DISTURBANCES IN SELF-CONCEPT
Infancy			
	• No self-concept at birth • Beginning differentiation of self and nonself	• Teach parents the critical importance of providing consistent and affectionate parenting. • Assess whether the parents have reasonable expectations of the infant: sleeping, eating, other awake behaviors.	• Unmet basic human needs • Lack of adequate body and sensory stimulation • Parents' lack of acceptance of the infant's appearance or behavior • Poor match between parent's and child's temperament or needs

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Childhood	• An intact body is important to the young child, who fears bodily mutilation. • During middle childhood, a sense of being trusted and loved, of being competent and trustworthy develops. • Differences between self and others are strong.	• If invasive procedures are indicated, explain simply to the child what is being done and offer the child support. • Assess the parents' ability to provide the type of developmental environment in which the child's self-concepts can evolve positively.	• Dysfunctional family • Too much or too little structure • Sensory perceptual impairments
Adolescence	• Development of secondary sex characteristics; rapid body changes • Sense of self is consolidated. • Emphasis on sexual identity • Parental influences on self-concept are often rejected; peers become more important; movement is toward development of own identity.	• Assess adolescent's self-knowledge and understanding of body changes. • Counsel adolescents regarding mature and healthy use of independence they crave. • Provide anticipatory guidelines regarding hazards to life, health, human functioning.	• Inability to accept body • Inability to resolve competing pulls to be both a child and an adult • Unhealthy peer pressure • Identity confusion
Adulthood	• Society places emphasis on intactness of body, fitness, energy, sexuality, style, productivity, sophistication, beauty. • Important to meet role expectations well.	• Assess how realistic the adult's expectations are and the incentive they provide for growth and development. • Assist patient to deal constructively with negative influences in self-image. • Preretirement counseling.	• Inability to fulfill conflicting role expectations • Failure to accept role responsibility (e.g., parenting responsibilities) • Unreasonable expectations • Irreversible body change related to trauma, illness • Unsatisfying job • Failure to develop new goals to give meaning and purpose to life • Multiple stressors
Later Adult Years	• Declining physical and possibly mental abilities • Multiple losses • Increasing dependency • Impending death • Diminished choices/options	• Assess how the older adult is adjusting to effects of aging. • Counsel regarding meaningful use of time. • Explore resources. • Assess depression, substance abuse. • Recognize and value older adults' life experience.	• Loss of significant work (retirement); feelings of uselessness • Death of spouse, significant others • Diminished physical attractiveness, strength, overall health • Multiple stressors • Fear of dependency • Change may be more difficult

Box 42-2 **Test Your Clinical Reasoning and Judgment**

Reflective Practice: Worries grow about the treatment of children who say they are transgender

In 2008, Andrea Davidson's 12-year-old daughter, Meghan, announced that they were "definitely a boy." Ms. Davidson says Meghan was never a tomboy, but the family doctor congratulated Meghan and asked what pronouns they have chosen, before writing a referral to the British Columbia Children's Hospital. "We thought we were going to see a psychologist, but it was a nurse and a social worker" says Ms. Davidson. "Within 10 minutes they had offered our child Lupron"—a puberty blocking drug. "They brought up the drug directly with our child, in front of us, without discussing it with us privately first." There was no mention of other mental health issues, which are known to increase the likelihood of gender dysphoria, the feeling that you are in the wrong body. "There was no therapy on offer, and we were just brushed aside when we raised it."

Meghan belongs to a wave of children across the Western world who have identified as transgender in recent years. America had 1 gender clinic in 2007; now it has more than 50. An increasing number of children are also de-transitioning, choosing to revert to their previous gender. Unfortunately, if children have already begun a medical transition, including hormone treatment, it can leave them infertile and unable to have a full sex life. [(December 12, 2020). Boys and girls. *The Economist*, 60–62.]

If you were caring for Meghan, what would your assessment priorities be, and which interventions/treatment plans should be offered?

History of Success and Failure

People with a history of repeated failure (in school, friendships, work, or marriage) may perceive themselves as failures and actually perpetuate this image by unconsciously encouraging others to treat them this way. They may come to fear success, and actually find it easier to fail even though they do not like themselves that way. Thus, failure influences a person's self-concept negatively (e.g., Sullivan's "bad-me" self-representation), and that negative self-concept causes the person to continue to fail. On the other hand, a series of successful experiences—especially when occurring in the context of an accepting, nurturing, caring relationship—may condition a person to strive for the next success, forging a positive self-concept that fosters an expectation of success and encourages the person to "make it happen."

Think back to **Melissa Motsky**, the struggling nursing student. Consider how multiple less-than-satisfactory life experiences may culminate in Ms. Motsky's sense of personal failure in areas such as academics, relationships, role performance in their family, and work experience.

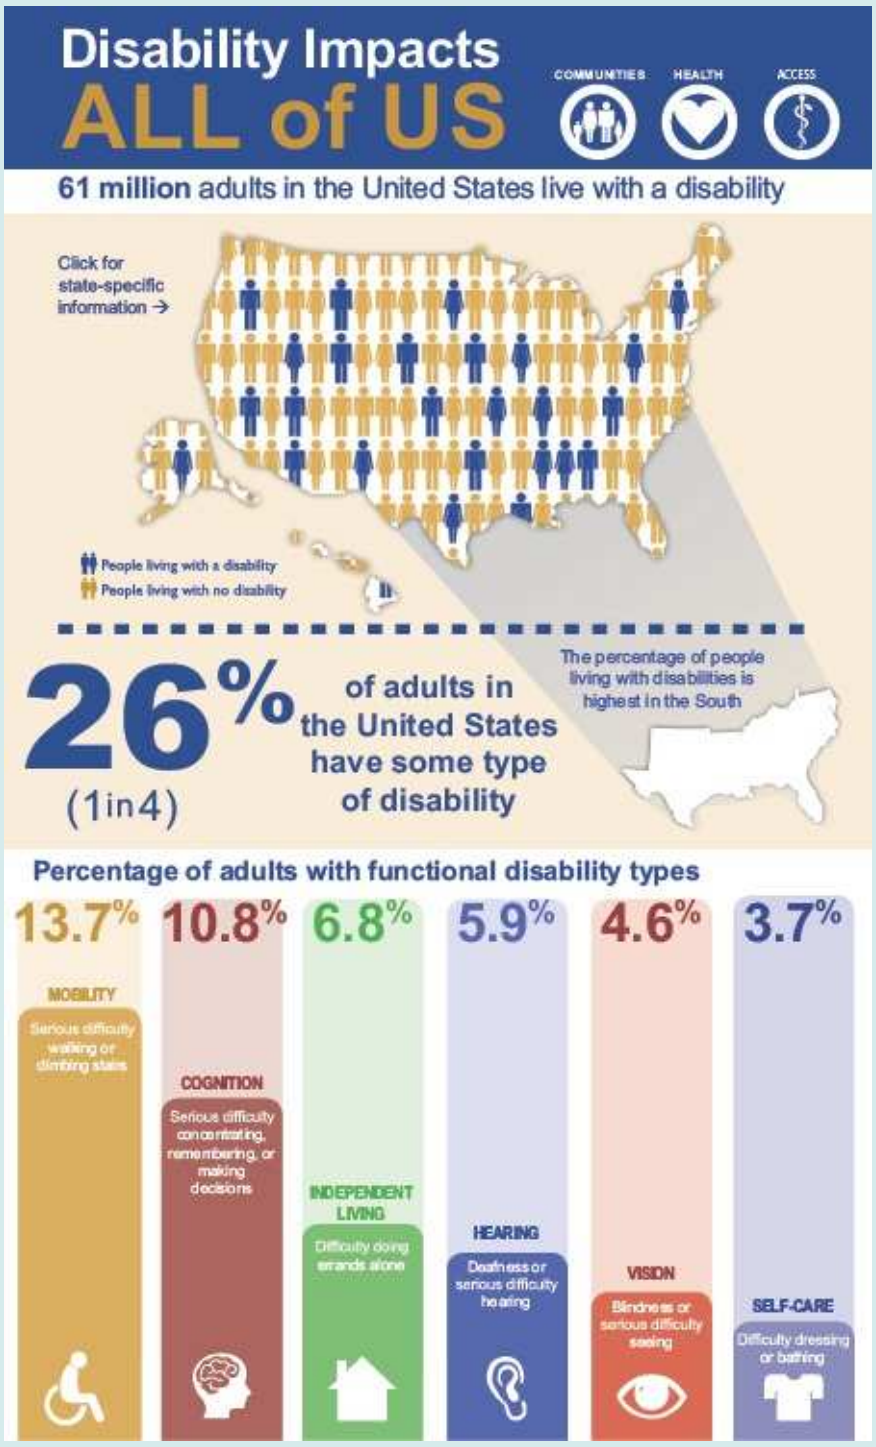
Crises or Life Stressors

Life stressors or crises (e.g., cyber bullying, marriage, divorce, acute or chronic illness, an exam, a new job or job loss, a gray hair, a fire) may call forth a personal response and mobilize a person's talents, resulting in good feelings about oneself, or it might result in emotional paralysis with diminished self-concept. People vary greatly in their perception of what constitutes a crisis or stressor, as well as the degree to which such experiences disrupt or diminish self-concept. However, major stressors place anyone at relative risk for maladaptive responses, such as withdrawal, isolation, depression, extreme anxiety, substance abuse, or exacerbation of physical illness. How the person perceives the stressor (threat, challenge, defeat) and the person's ability to mobilize personal strengths and other resources are determined largely by that person's self-concept, which, in turn, is influenced by the response the person chooses.

Aguilera (1998) described three factors that determine a person's response to crisis: (1) the person's perception of the event or situation, (2) the person's situational supports (external resources), and (3) the coping mechanisms the person possesses (internal resources). All of these factors are related to self-concept. The degree of strength a person has in each area is related to the person's pre-crisis self-concept. Similarly, each of these factors can alter self-concept either positively or negatively during or after the crisis. Intervention to strengthen any of these three areas can help people better cope with crisis and emerge with enhanced self-concept.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Recall **Anthony Santorini**, the patient who had an amputation. To promote an enhanced self-concept, the nurse would need to assess their perception of the situation and their coping mechanisms to gain further insight into Mr. Santorini's self-concept. In addition, the nurse would need to investigate the support systems available to Mr. Santorini, such as family, friends, and community resources, which might be helpful in fostering a more positive self-concept.



Aging, Illness, Disability or Trauma

Many people take a healthy body for granted. Society encourages a kind of denial of the eventuality of aging, chronic illness, and the necessity to integrate crisis and change throughout each person's lifetime. Society emphasizes and rewards youth, health, and narrow norms for physical attractiveness while devaluing seniors, those with chronic illness, and those whose appearance does not correspond to celebrity standards. Thus, a sudden illness, trauma, or bodily disfigurement, or even the suggestion of disease, as well as signs of the aging process may pose serious threats to the self. People vary greatly in their response to aging, illness, disability, and trauma (Fig. 42-4). This is due to the threats to self-concept and internal beliefs about the self that these conditions may pose. See the accompanying Vulnerable Population Alert and reflect on your ability to competently and compassionately care for persons with disabilities.

FIGURE 42-4. An illness or alteration in function may present challenges that affect a patient's self-concept. Changes may be positive or negative. How family and professional caregivers respond is critical.

Unfolding Patient Stories: Marvin Hayes • Part 2

Think back to **Marvin Hayes** from Chapter 39, who is 43 and married. He underwent surgery for rectal cancer requiring a permanent colostomy. What effect can a colostomy have on his self-concept? How would the nurse assess for a disturbance in self-image caused by the colostomy? If a body image disturbance, low self-esteem, or ineffective role performance is identified, what nursing interventions can help Marvin modify a negative self-concept and adapt to his colostomy?

Care for Marvin and other patients in a realistic virtual environment: *vSim for Nursing* (thepoint.lww.com/vSimFunds). Practice documenting these patients' care in DocuCare (thepoint.lww.com/DocuCareEHR).

Vulnerable Population Alert: Persons With Disabilities

Approximately 61 million adults in the United States live with a disability. A disability is any condition of the body or mind (impairment) that makes it more difficult for the person with the condition to do certain activities (activity limitation) and interact with the world around them (participation restrictions). According to the World Health Organization, disability has three dimensions:

- **Impairment** in a person's body structure or function, or mental functioning; examples of impairments include loss of a limb, loss of vision or memory loss.
- **Activity limitation**, such as difficulty seeing, hearing, walking, or problem solving.
- **Participation restrictions** in normal daily activities, such as working, engaging in social and recreational activities, and obtaining health care and preventive services.

Disability is especially common in these groups:

- 2 in 5 adults ages 65 years and older have a disability
- 1 in 4 women have a disability
- 2 in 5 Non-Hispanic American Indian/Alaska Native individuals have a disability

Adults living with disabilities are more likely to have obesity (38.2%), smoke (28.2%), have heart disease (11.5%), and have diabetes (16.3%).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Health care access barriers for working-age adults include:

- 1 in 3 adults (18 to 44 years) with disabilities do not have a usual health care provider
- 1 in 3 adults with disabilities have an unmet health care need because of cost in the past year
- 1 in 4 adults with disabilities did not have a routine checkup in the past year. (*Source*: Centers for Disease Control and Prevention. *Disability impacts all of us*. https://www.cdc.gov/ncbddd/disabilityandhealth/infographic-disability-impacts-all.html)

Have you ever cared for an individual with disabilities? How competent and confident are in meeting their needs? What does thoughtful person-centered care "look like" for individuals with mobility, cognition, independent living, hearing, vision, and/or self-care disabilities? Are there particular challenges to their self-esteem? You may want to check out these resources:

- The US Centers for Disease Control and Prevention: http://www.cdc.gov/ncbddd/disabilityandhealth/women.html/
- Women's Health.gov: http://www.womenshealth.gov/search/node?keys=disabilities

NURSING PROCESS FOR PATIENTS WITH ALTERATIONS IN SELF-CONCEPT

Nurses who role-model good health behaviors are more effective teachers. Use the display, Promoting Health 42-1, for yourself before using it with others. Before you can successfully identify and resolve self-concept disturbances in patients, you must be comfortable with yourself and possess an adequate self-concept.

Assessing

The nurse assessing a patient's self-concept focuses on personal identity, personal strengths, body image, self-esteem, and role performance. A general assessment of self-concept should be included in every comprehensive nursing assessment. It is as important to identify and label a patient's positive self-concept as it is to note actual or potential problems.

Patients experiencing illness or trauma resulting in body disfigurement, altered functioning, or life crises that arrest development and thwart the achievement of life goals are at high risk for problems related to self-concept and should be assessed more carefully. If potential problems surface during the interview, a more thorough assessment should be carried out.

The accompanying Focused Assessment Guide highlights elements common to any self-concept assessment and high-risk factors, as well as questions and approaches that can be used in assessing self-concept.

When conducting a self-concept assessment, be aware of the limitations of self-reporting. Patients may give what they believe are the desired or socially acceptable responses to interview questions. "Why, of course I like myself. I'm a pretty good person. Yes, I have friends." For this reason, evaluate the patient's responses in relation to your observations about the patient and what you know about the patient from other sources. When the nursing assessment reveals a clustering of these behaviors, discuss this finding with the patient. This is especially true when there is a discrepancy between the patient's words and behavior. "You've told me that you feel in control of your situation right now and are committed to the treatment plan, but I notice you're not taking your medications regularly, and you did mention that you are drinking more heavily…."

Personal Identity

When assessing self-concept, the information needed first is the patient's description of self. **Personal identity** describes a person's conscious sense of who they are. "How would you describe yourself to others?" Pay special attention to the labels used by the patient and the order in which they appear. A simple exercise consists of asking patients to "make a list of 10 labels that you believe identify yourself (e.g., gay man, student, Italian American person, opera fan, premedicine major). Put the most important label first, and then list the others in order of decreasing importance. What if the order were reversed? To what extent do you think your way of organizing information about yourself affects your behavior?"

It is important to discover whether people are comfortable with their perceived identity. Developmental changes,

trauma, and cultural and gender dysphoria may all place a patient at risk for personal identity disturbances.

Personal Strengths

Many patients focus naturally on their deficiencies; asking pointed questions about personal strengths can help a patient identify positive factors:

"What are some of your personal strengths … qualities you are proud of … things you do well?"

"What has helped you cope in the past when things were tough?"

Promoting Health 42-1

SELF-CONCEPT

Use the assessment checklist to determine how well you are meeting your need for positive self-concept. Then develop a prescription for self-care by choosing appropriate behaviors from the list of suggestions.

Assessment Checklist

☐ almost always ☐ sometimes ☐ almost never

☐	☐	☐	1. I have established appropriate expectations and goals for myself.
☐	☐	☐	2. I have effective and satisfying relationships with others.
☐	☐	☐	3. I cope effectively with change and loss.
☐	☐	☐	4. I accept and feel good about myself.

Self-Care Behaviors

1. Accept normal variations in physical appearance and capabilities.
2. Use problem-solving and decision-making strategies to define expectations and set goals.
3. Set priorities and accept that no one person can be all things to all people.
4. Learn from past mistakes and then forget them; carrying around "excess baggage" is unhealthy.
5. Emphasize strengths and abilities in self.
6. Take an active part in group activities in school, work, church, or the community.
7. Volunteer time, talents, or services.
8. Avoid excessive alcohol and drugs.
9. Live life one day at a time.
10. Get help for self-concept disturbances that interfere with healthy social and professional activities.

Focused Assessment Guide 42-1

SELF-CONCEPT

Factors to Assess	High-Risk Factors	Questions and Approaches
Personal identity	• Developmental changes • Trauma • Gender dysphoria • Cultural dissonance	*How would you describe yourself to others?* • Personal characteristics and traits • Strengths • Fears
Body image	• Loss of body part or function • Disfigurement • Developmental changes	*Describe your body to me.* *What do you like most/least about your body?* *Is there anything about your body that you would like to change?*
Self-esteem	• Unhealthy interpersonal relationships • Failure to achieve developmental milestones • Failure to achieve life goals • Failure to live up to personal moral code • Sense of powerlessness	*Tell me something about your sense of satisfaction with yourself.* *Tell me about your relationships with others.* *Who would you like to be?* *Who or what has influenced your self-expectations?* *Are these expectations realistic?* Significance: *What is your response when you feel unloved or unappreciated by those who are important to you?* Competence: *How do you feel about your ability to do the things in life that are important to you?* Virtue: *To what degree are you satisfied with the way you are able to live up to your moral standards?* Power: *To what extent do you feel able to control what happens to you in life? How does this make you feel?*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Role performance	• Loss of valued role • Ambiguous role expectations • Conflicting role expectations • Inability to meet role expectations	*Many of us "wear many hats." What roles (spouse, parent, student, athlete, nursing aide, dancer) are most important to you?* *How do you feel about your ability to do all the things your roles demand of you?* *Are these roles satisfying for you?*

Body Image

Body image is the person's subjective view of their physical appearance. Body image disturbances can be expected with any alteration in bodily appearance, structure, or function.

When a disturbed body image is suspected, carefully interview and observe the patient to identify the nature of the threat to the person's body image (functional significance of the part involved, importance of physical appearance, visibility of the part involved), the meaning the patient attaches to the threat, the adequacy of the patient's coping abilities, response of family members and significant others, and help available to the patient and patient's family.

Assess the patient's response to the deformity or limitation, including changes in independence–dependence patterns and in socialization and communication.

RESPONSE TO MALFORMATION OR LIMITATION

- *Adaptive responses:* Patient exhibits signs of grief and mourning (shock, disbelief, denial, anger, guilt, acceptance).
- *Maladaptive responses:* Patient continues to deny and to avoid dealing with the deformity or limitation, engages in self-destructive behavior, talks about feelings of worthlessness or insecurity, equates deformity or limitation with whole person, shows a change in ability to estimate relationship of body to environment.

INDEPENDENCE–DEPENDENCE PATTERNS

- *Adaptive responses:* Patient assumes responsibility for care (makes decisions), develops new self-care behaviors, uses available resources, interacts in a mutually supportive way with family.
- *Maladaptive responses:* Patient assigns responsibility for their care to others, becomes increasingly dependent, or stubbornly refuses necessary help.

Recall **Anthony Santorini**, the 44-year-old man who had an amputation. The patient voiced concerns that he was not "whole" anymore. The nurse would need to assess the underlying factors associated with this feeling. Is the feeling related to the actual loss of a body part, fear of further disfiguration from continued complications, inability to function independently, or fear of how others will react to the loss? Additional inquiry is needed to determine the value Mr. Santorini places on physical appearance and the meaning he attaches to their extremities, such as ability to walk, work, or just get around the house or their environment. The nurse could then work with the patient and assist with adapting to the loss of their leg. Incorporating information about the use of a prosthesis may be helpful as they begin to adapt to their body change.

Self-Esteem

When patients share their self-perceptions, use the opportunity to ask questions about whether patients like themselves, and whether they are pleased with their expectations and the progress they are making to realize these expectations. For example, you might state:

"Tell me what you like about yourself."
"What would you change about yourself if you could?"

You can obtain a quick indication of a patient's self-esteem by using a graphic description of self-esteem as the discrepancy between the "real self" (who we think we really are) and the "ideal self" (who we think we would like to be). Have the patient plot two points on a line—real self and ideal self (Fig. 42-5). The greater the discrepancy, the lower the self-esteem; the smaller the discrepancy, the higher the self-esteem.

A person's ideal self may differ dramatically from the current sense of self and may positively or negatively

influence behavior and personal development. If indicated, question the patient about self-expectations:

"You've told me something about who you are and how you view yourself now. Tell me who you would like to be in the future."

"What life goals are important to you?"

"Where do you see yourself 5 years from now? In 10 years?"

"Are these expectations realistic?"

"Are your expectations stemming from who you would like to be or from who you think you should be?"

"Who or what has influenced your self-expectations?"

Such questions help assess whether the patient possesses life goals that are positively motivating personal development.

Identify any unrealistic expectations and explore their source with the patient. For example:

"You seem to feel that it is necessary to be all things to all people—no matter what this costs you. How might this belief have developed? Is it helpful to you?"

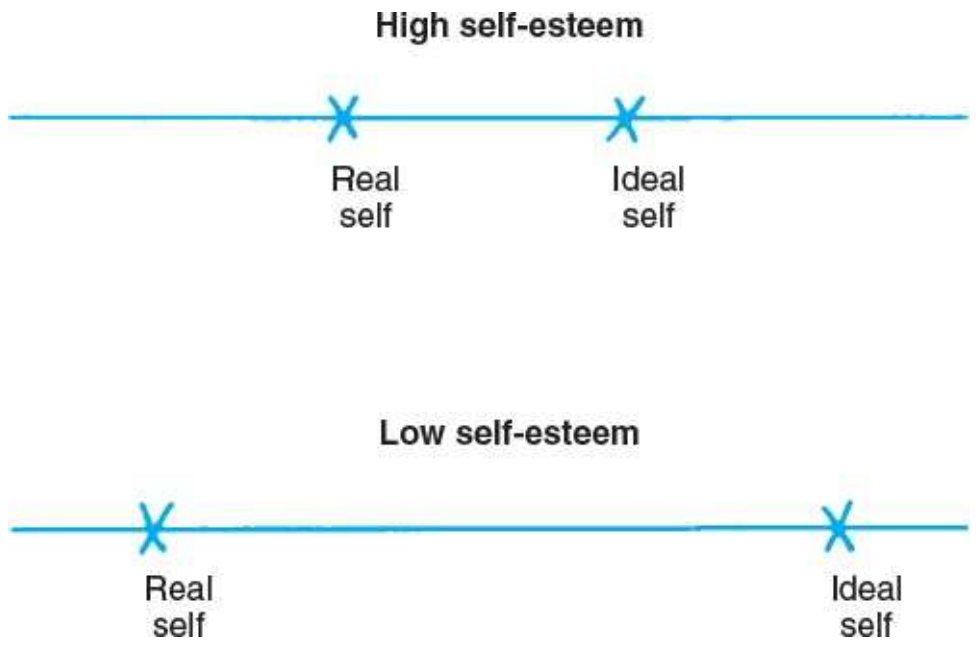

FIGURE 42-5. Patients who perceive their real self as relatively close to the ideal self have high self-esteem. Patients who perceive their real self as far from the ideal self have low self-esteem.

"What I'm hearing is that your performance must always be perfect, that although you allow others to make mistakes, you cannot allow yourself this luxury. Tell me more about this."

"You state you have no goals for the future. When you wake up each morning, what gets you out of bed? What keeps you moving?"

If a more detailed assessment is needed, the concepts of socialization and communication, significance, competence, virtue, and power should be explored next.

SOCIALIZATION AND COMMUNICATION

Responses to socialization and communication may be adaptive or maladaptive:

- *Adaptive responses:* Maintains usual social patterns, communicates needs and accepts offers of help, serves as support for others.
- *Maladaptive responses:* Isolates self, exhibits superficial self-confidence, is unable to express needs (becomes hostile, ashamed, frustrated, depressed).

To assess the quantity and quality of the patient's interpersonal relationships, which helps identify the person's level of social support and relatedness, you might ask:

"Who do you feel is important to you?"

"Is there anyone you feel you can depend on for help if you need it?"

"How do you feel about your relationships?"

"Tell me about changes you've noticed in your ways of meeting and interacting with others."

"Many people have 'people' problems. Are your relationships causing you any problems right now?"

SIGNIFICANCE

To assess the patient's feelings of significance, you might ask:

"Are there people in your life with whom you share a close relationship?"

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

"To what extent do you feel loved and approved of by the key people in your life?"

"Does it bother you when you feel unloved or when others fail to appreciate you?"

"In what ways do you let family members and friends know that you like them or are proud of their accomplishments?"

COMPETENCE

To assess the patient's feelings of competence, you might ask:

"What are the things you need to do to feel important?"

"Is anything interfering with your ability to execute these tasks? How does this make you feel?"

"How important to you is it to feel that others value your work?"

VIRTUE

To assess the patient's sense of virtue, you might ask:

"Tell me something about the moral–ethical principles that govern your life."

"How must you live to describe yourself as a 'good' person?"

"Describe any difficulties you experience in living up to your moral principles that you would like to discuss."

"In what ways can the nurses help you to live better according to your moral standards?"

POWER

To assess the patient's sense of power, you might ask:

"How important is it to you to 'be in control' of your life (health)?"

"To what extent did you feel 'in control' of your life (health) before this illness (trauma, crisis)?"

"To what extent do you feel 'in control' of your life (health) currently?"

"What is it that makes you feel not in control?"

"How might you change this? How can nurses help you to develop and gain more control?"

Role Performance

We all play many roles. Life roles such as our occupation or profession can constitute a major portion of our identity. Our ability to successfully live up to societal as well as our own expectations regarding role-specific behaviors, or our **role performance**, is easily compromised by illness and injury. Often, illness or developmental processes such as aging make it necessary to alter or relinquish previous roles. In general, people experience such alterations as major losses. Thus, all people whose roles are altered or compromised are at risk for disturbances in self-concept. Role performance may also be affected by role ambiguity (failure to completely and accurately understand what a role demands), role stress (disparity between what one believes the role demands and what one is able to offer), and role overload (limited time because of other commitments makes it impossible to meet realistic role expectations). With any patient who has experienced compromised role performance, use the following questions:

"What major roles describe you—son, daughter, spouse, parent, employer or employee, student, club member, and so on?"

"How important is it to you to be good in each of these roles?"

"Tell me how successful you think you are in each of these roles."

"What roles or expectations would you change if you could?"

"What new skills or behaviors might be necessary to help you resume or modify current roles?"

"What is it like for you to lose a role that's been important to you?"

"How can I help you identify other role options or direction?"

Think back to **Delores Sparks**, the woman with advanced lung cancer now living with her daughter. The change in living situation and dependence on her daughter for everyday activities has definitely affected the patient's role performance. Once living alone and fairly self-sufficient, Mrs. Sparks now relies on her daughter. The role performance questions would be extremely important to ask Mrs. Sparks to determine the actual impact her illness and change in living situation has had on her self-concept.

Diagnosing Actual or Potential Health Problems and Needs

An assessment of a patient's self-concept may lead to the identification of one or more actual or potential health problems and needs related to self-concept. Following the formulation of the actual or potential health problems and needs, the nurse communicates findings to other nursing and health care professionals through the use of the written and spoken word. The written actual or potential health problem or need becomes a permanent part of the patient's health record.

The International Classification for Nursing Practice (ICNP) identifies several actual or potential health problems that may be identified by nurses:

- Negative Self-Image
- Disturbed Body Image
- Disturbed (or Risk for Disturbed) Personal Identity
- Chronic (or Risk for Chronic) Low Self-Esteem or Situational (or Risk for Situational) Low Self-Esteem
- Impaired Role Performance

Common etiologic factors and potential signs and symptoms for some of these health problems are found in the accompanying box, Examples of Actual or Potential Health Problems and Needs: Self-Concept on page 1750.

The ICNP lists as a positive diagnosis and health outcome Positive Self Image (body image, personal identity, and self-esteem.

Important Distinctions

When assessment data point to an alteration in self-image, the first task is to determine whether the altered self-concept is the problem, the cause of the problem (etiology), or merely a sign that a problem exists. It is important to make an accurate determination because this directs the outcomes developed for the patient and related nursing interventions.

Examples of Actual or Potential Health Problems and Needs

DISTURBANCES IN SELF-CONCEPT

Actual or Potential Health Problems and Needs	Possible Etiologic Factors	Potential Signs and Symptoms
Disturbed Body Image	• Illness • Trauma • Disability • Aging	• "I don't recognize my body anymore and it certainly doesn't work like it should!" • "I can't even imagine my husband wanting to have sex with me. I feel so different after losing a breast." • Avoids looking at their body • Avoids touching their body
Risk for Situational Low Self-Esteem	• Sudden alteration in body image or functioning	—

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

	• Alteration in social role • Behavior inconsistent with values • Decrease in control over environment • Inadequate recognition from significant others • Unrealistic self-expectations	
Positive Self-Image	—	• Acceptance of limitations • Acceptance of strengths • Actions congruent with verbal expressions • Expresses confidence in abilities • Expresses desire to enhance role performance or self-concept • Expresses satisfaction with sense of worth

Source: International Council of Nurses. (2019). Nursing diagnosis and outcome statements. International Classification for Nursing Practice (ICNP) Catalogue. https://www.icn.ch/sites/default/files/inline-files/icnp2017-dc.pdf

Consider **Delores Sparks** and the following problem statements:

Situational Low Self-Esteem related to perceived failure in role of mother and grandmother; signs and symptoms: feelings of being a bother and not good for anything anymore. Assessment data point to a disturbance in self-esteem as the priority problem. Nursing energies will be directed to helping the patient evaluate herself positively despite the stress of the illness and loss of independence.

Impaired Health Maintenance related to decreased self-esteem; signs and symptoms: feelings of depression. Here, low self-esteem is contributing to the patient's problem of failing to maintain her health as much as possible by following through with actions, and by voicing thoughts of ending her own life. Nursing energies will be best directed to improving the patient's use of health resources, including helping her to value herself enough to choose healthy behaviors.

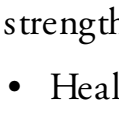
Difficulty Coping related to difficulty accepting changes in health status and role resulting from terminal illness; Signs and symptoms: low self-esteem statements ("I feel like an old dish rag, not good for anything anymore") and thoughts about ending her life ("since God isn't doing it"). Here, low self-esteem statements are the cues that led to the identification of the problem statement. One of the criteria used to evaluate nursing intervention to increase the patient's coping skills will be a reduction in or elimination of low self-esteem statements.

Outcome Identification and Planning

With all patients, nursing interventions need to be supportive of the following patient outcomes:

The patient will:

- Describe self realistically, identifying both strengths and deficiencies
- Verbalize realistic expectations for self, based on who the patient would like to be
- Verbalize that self is liked, or at least "OK"
- Communicate feelings and needs in a way that is comfortable and effective in meeting needs
- Nurture relationships in which needs for love and worth are mutually met (significance)
- Assume role-related responsibilities with confidence (competence)



- Express satisfaction with ability to live according to their moral–ethical standards (virtue)
- Demonstrate confidence in ability to accomplish what is desired (power)

The following are sample outcomes for patients with specific disturbances in self-concept:
The patient will:

- Describe the relation between self-concept and behavior
- Identify faulty thinking that reinforces a negative self-concept (distortions and denials, faulty categorizing, inappropriate standards)
- Integrate positive self-knowledge into self-concept
- Report feeling better about himself or herself

Implementing

Nursing interventions to assist patients to develop and maintain a positive self-concept can vary tremendously from one patient to another.

Nurse Self-Care Alert

Remember: You must be comfortable with your own self-concept before you can address problems in patients.

Specific nursing strategies addressed in this section include helping patients identify and use personal strengths, helping at-risk patients maintain a sense of self, enhancing or modifying the self-concept, developing a positive body image, and working with parents and educators to develop self-esteem in children, adolescents, and older adults.

Helping Patients Identify and Use Personal Strengths

When confronted with a major stressor, many people forget that they have histories of successful coping and numerous personal strengths. Patients at high risk for giving up are those with low self-esteem or multiple stressors they perceive as overwhelming.

Although attributing strength to a patient sounds like something nurses would do naturally, nurses frequently fall into the trap of "doing" for patients (i.e., solving their problems rather than helping them to identify and tap their personal power and strengths). Moreover, patients continually instruct nurses about how they should be perceived, and some patients successfully communicate a manipulative helplessness that encourages the nurse to take charge. An appropriate nursing response in this case is, "I wonder why you want me to speak with your health care provider about treatment alternatives. I'm sure you would feel much better hearing this information firsthand. If you'd like, I will stay here while you talk with the health care provider."

Patients experiencing powerlessness may need help to recognize their strengths (Fig. 42-6). Examples of personal strengths that might better equip a person to respond to life's challenges include:

- Healthy, functioning body
- Ability to adjust to or function with chronic bodily malfunction
- Cognitive abilities
- Positive self-concept
- Interpersonal skills
- Sense of meaning and purpose in life
- Belief system
- Social support network
- Meaningful work

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

FIGURE 42-6. The nurse helps the patient recognize their self-worth and strengths.

- Hobbies and other interests
- Education
- Life experience and a past history of effective coping
- Good sense of humor
- Spirituality
- Healthy nutritional state
- Ability to make decisions

If you search for "Self-Esteem Worksheets" online, you will find many resources to help your patients build their self-esteem.

Specific strategies that can be used to help patients identify and use personal strengths include the following:

- Encourage patients to identify their strengths.
- Replace self-negation with positive thinking.
- Notice and reinforce patient strengths.
- Encourage patients to will for themselves the strengths they desire and to try them on.
- Help patients cope with necessary dependency resulting from aging or illness.

Helping At-Risk Patients Maintain a Sense of Self

People who are acutely ill are often separated not only from their strengths, but also from any real sense of self. This occurs largely because, as patients in health care facilities, they are removed from their personal roles, environments, and belongings, and stripped of their individuality by staff caring for them. One patient, a college president who was recovering from serious complications after surgery for ovarian cancer, shared the following:

> When I first got sick, it didn't matter how people treated me because I knew who I was. As I've grown sicker and weaker, I become whatever people make me. If a nurse walks in here and moves me like meat, I become a slab of meat. My sense of self seems more and more dependent on how people respond to me.

Help patients maintain a sense of self and worth by doing the following:

- Use looks, speech, and judicious touch to communicate worth.
- Acknowledge the patient's status, roles, individuality.
- Speak to the patient respectfully and in a nonpatronizing manner.
- Converse with the patient about the patient's life experience.
- Address the patient by preferred name whenever entering the patient's room.
- Offer the patient a simple explanation before initiating any procedure.
- Move the patient's body respectfully if the patient is unable to do this.
- Respect the patient's privacy and sensibilities.
- Acknowledge and allow expression of negative feelings.
- Help the patient to recognize strengths and explore alternatives.

QSEN PATIENT-CENTERED CARE

You can help patients by respecting them and encouraging them to express their values, preferences, and expressed needs. This enables you to communicate patient values, preferences, and expressed needs to other members of the health care team.

Always keep in mind that patients are *people*, first and foremost. See Through the Eyes of a Nurse. A person's illness does not define who that person is. Too often, health care professionals tend to focus primarily on a patient's illness, and the whole person is forgotten or ignored, with potential negative consequences for that patient's sense of self, such as lack of motivation to learn or execute important health care behaviors. The way nurses care for patients can directly affect self-concept; self-concept, in turn, directly affects health. Thoughtful person-centered nursing care does not require additional nursing time or energy. It does require from the nurse continual reaffirmation that nursing is a thoughtful, person-centered profession, and that nothing is more important at any moment of a nurse's workday than the person being served. Be sure to check out Box 47-2, Steps for being a healing presence, in the chapter on Spirituality.

Teaching Self-Compassion

Self-compassion is a powerful tool that nurses can use for themselves and for patients. When we see others who are suffering and feel their plight, when we are moved by the suffering of others and want to respond in a helpful way, we are being compassionate.

Nurse Self-Care Alert

Self-compassion scholar Dr. Kristin Neff writes that **self-compassion** involves acting the same way toward yourself when you are having a difficult time, fail, or notice something you don't like about yourself. "Instead of just ignoring your pain with a 'stiff upper lip' mentality, you stop and tell yourself, 'this is really difficult right now; how can I comfort and care for myself in this moment?'" Instead of mercilessly judging and criticizing yourself for various inadequacies or shortcoming, self-compassion means you are kind and understanding when confronted with personal failings—after all, who ever said you were supposed to be perfect?"

Through the Eyes of a Nurse

Picture Those You Love

Over the course of my nursing career, I've seen many different approaches used to instill a focus on improving patient satisfaction, some far better than others. I just experienced what was, for me, the best one yet. Our speaker asked all attendees to take out their cell phones and find a picture of a loved one. She then asked participants to partner with someone else and, in turn, tell each other about their loved ones.

Knowing the session topic was on patient experience, many of us had a sense of foreboding about what might happen next. The speaker smiled and reminded us that every person we contact in health care is pictured in someone's cell phone or wallet. She simply suggested that we keep in mind the feeling we have for those *we* love when we encounter others.

In our health care world, we often erect walls around our hearts to enable enough professional distance to keep us focused and objective despite difficult or tragic circumstances. Those walls are a survival strategy. They reduce our vulnerability to emotional pain from constantly being immersed in situations that those outside of health care can hardly fathom. Much like scar tissue, however, the walls can become too thick.

Each of whom has had the unfortunate experience of being on the other side of the bed rails, whether as a patient or as a family member, wants to feel a caring connection. Our patients do, too. We can't lose sight of that. Distance and vulnerability are on two different ends of the caring spectrum. We each need to find a balance that doesn't exclude patients. When in doubt, consider whose picture is on your cell phone.

—Linda Laskowski-Jones, Christiana Care Health System

You may want to try out the official self-compassion website (http://self-compassion.org) for helpful self-compassion practices (guided meditations and exercises).

Modifying a Negative Self-Concept

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

The time is ripe for change when a patient realizes that a negative self-concept is hindering personal development related to health and wellness care. One option is using a cognitive-behavioral approach to assist the patient in modifying self-concept. The general principle is to help the patient alter their perspective of a situation from a more negative view to a more positive view, a process known as "reframing." Once a person can view their situation more positively, a wider variety of behavioral options, coping mechanisms, or internal or external supports can be identified and activated. While any person's self-concept is usually firmly entrenched and naturally resists change, you should remain optimistic that change is possible, if even in small increments. Helpful nursing interventions include the following:

- Help the patient identify and describe in detail how the patient thinks and feels about situations related to self-concept. Identify the patient's faulty thinking patterns.
- Explore with the patient alternative ways of viewing the same situation—that is, reframe the patient's thinking about the situation.
- Teach the patient to "red flag" faulty thinking behavior as soon as the patient is aware of it. The goal is to replace the negative thinking and self-talk with thinking and self-talk that will develop a more positive self-image.
- Help the patient explore the positive dimensions of the self that the patient wishes to develop, and incorporate this new knowledge into the self-concept.

Developing a Positive Body Image

Interventions for body image disturbances vary according to the nature of the disturbance. Interventions may include a combination of the following:

- Express interest in and acceptance of the patient through verbal and nonverbal expression. Allow the patient to share their feelings openly. Sitting quietly by the patient for a few minutes, with a few words such as, "How are things?" or "Tell me what's going on with you" communicates to the patient your willingness and readiness to share the patient's experience.
- Explore with the patient their feelings about altered body image and the patient's perceptions about the meaning and consequences of such alteration.
- Support the patient through the various stages of loss, grief, and mourning (shock, disbelief, denial, anger, guilt, acceptance), remembering that there is no one right way to proceed through these stages. Rather, patients may move fluidly in and out of various stages, sometimes returning to earlier stages. Some patients may need to learn that it is okay to cry, to be angry, or to feel depressed.
- Use play therapy with children so that they can describe their feelings and work through their grief using the nonthreatening medium of dolls or animals.
- Use self-reflection to gain awareness of your attitudes and feelings toward the patient. Be careful not to let facial expressions, words, or body positioning communicate to the patient disgust, fear, or rejection.
- While communicating support to the patient who is slow to develop and use appropriate self-care behaviors, firmly insist that the patient participate in their care to the extent that the patient is able. Whenever possible, provide the patient with honest answers to questions or put the patient in touch with the appropriate person to give the answers.
- Strengthen the patient's decision-making ability by honestly exploring alternatives; help the patient to imagine living with the consequences of different courses of action.
- Reinforce the patient's personal strengths and help the patient and family to identify all possible resources.
- Assess the response of the patient's significant others and intervene if they negatively influence the patient.

Developing Self-Esteem in Children and Adolescents

Nurses who work in practice settings where they have access to groups of parents, adult caregivers, or teachers can offer specific guidelines for creating developmental environments that build high self-esteem. Box 42-3 (on page 1754) offers five strategies for building self-esteem in children. Because some parents and educators may not have experienced these aids to personal growth themselves, it is beneficial to role-model these behaviors when interacting with children.

Important learning tasks for children include understanding and accepting themselves, their feelings, and others; independence; goals and purposeful behavior; mastery, competence, and resourcefulness; emotional maturity; and choices and consequences.

Enhancing Self-Esteem in Older Adults

The many losses associated with aging (e.g., diminished strength and physical health, interpersonal losses, retirement, shrinking income) make older adults especially vulnerable to disturbances in self-concept, particularly chronic low self-esteem. Society's generally negative view of aging compounds the problem. When interacting with older adults, employ the following interventions to enhance and maintain self-esteem in this population:

- Identify your own attitudes and feelings about aging and older adults.

- Address seniors respectfully, communicating that you take their concerns seriously.
- Respect and affirm seniors' intellect, individuality, personal strengths, culture, and spirituality.
- Adjust your communication style to accommodate any sensory or cognitive deficits.
- Encourage sharing of life experiences.
- Assist the person to identify strengths and coping mechanisms to deal with problems.

Box 42-3 **Building Self-Esteem in Children**

Strategy 1: Looking at the Positive and the Negative

Instruct parents to write an honest description of their child for a stranger. Next, have the parents underline the child's positive and negative qualities.

To reinforce the positive qualities, encourage the parents to (1) notice examples of ability in many different circumstances and point this out to the child; (2) find occasions to frequently and honestly praise the child; and (3) give the child frequent opportunities to show their abilities.

To address the negative qualities constructively, have the parents ask themselves: (1) What need is being expressed by this behavior? (2) Can I see a positive quality being expressed by this behavior? (3) How can I help my child express this quality and meet their needs in a more positive way?

Advise the parents to reexamine the list of negative qualities and ignore those that are merely a matter of taste, preference, or personal style—and not really negative in a harmful manner.

Strategy 2: Listening

The following guidelines can help parents use listening to communicate to a child, "You are important. What you say matters to me. You matter to me."

1. Make sure that you are ready to listen.
2. Give your child your full attention.
3. Minimize distractions.
4. Be an active listener.
5. Invite your child to talk.

Listen for the point of a child's story: "What is she trying to tell me? Why is this important to him?" Don't feel that you have to fix things. Listen for and respond to the feelings.

Strategy 3: Using the Language of Self-Esteem

The following concepts may help parents understand how to use language that builds self-esteem:

Feedback that enhances self-esteem has three components: (1) a description of the behavior (describe the behavior without judging it); (2) your reaction to the behavior (language that shares something about yourself); and (3) acknowledgment of the child's feelings. For example: "Thanks for playing with your brother tonight [*description*]. I was wondering how I was going to pay attention to our guests if he got fussy and was really grateful when I noticed that you kept him occupied and happy [*reaction*]. I know that there were other things you might have enjoyed doing more [*acknowledgment*]."

To give correction using the language of self-esteem, (1) describe the problematic behavior, (2) state a reason for the behavior change, (3) acknowledge the child's feelings, and (4) offer a clear statement of what is expected.

- *Attacking communications:* "Don't let me ever hear you talk that way to your mother again."
- *Language of self-esteem:* "I overheard you telling your mom that she should 'Get a life and get off your case.' (*description*). When you talk like that it just makes people angry or sad, which isn't very helpful (*reason for behavior change*). You probably feel like you are being picked on, and we may have some expectations that are different from those of your friends' parents. I hope you know that this is because we love you and want the best for you [*acknowledgment*]. In the future, try to talk to others with the same respect you'd like others to show you [*statement of expectation*]."

Avoid using the following destructive language styles, which tear down self-esteem: overgeneralizations ("You *never* come home on time!"), the silent treatment, and vague or violent threats.

Strategy 4: Helping Children Meet Expectations

To help children meet expectations, advise parents as follows: (1) Be sure that your expectations are reasonable and appropriate for your child's age. (2) Plan ahead. (3) Be clear about your expectations. (4) Focus on the positive. (5) Provide choices when possible. (6) Provide rewards.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Strategy 5: Promoting a Feeling of Success

To help children have the courage to try new types of experiences, which results from successfully meeting challenges, advise parents to (1) let a child know what to expect; (2) let your child practice the necessary skills; (3) be patient; and (4) make it safe to fail.

- Provide a safe environment for older adults to communicate such concerns as interpersonal or physical loss, feelings about illness and death, sexuality, or financial issues.
- Advocate for seniors needing help in attaining services necessary to meet their health care needs.
- Explore the personal meaning of dependency for the person, and help seniors adapt both physically and emotionally to any necessary dependency.

The Focus on the Older Adult box describes nursing interventions to promote self-esteem in older adults.

Evaluating

Nurses who are sensitive to the relationship between self-concept and general well-being consistently evaluate the effect the nursing care plan has on the patient's self-concept. When the care plan includes specific interventions to assist patients with disturbances in body image, self-esteem, role performance, and personal identity, listen carefully to the patient's self-report and observe patient behaviors to see if the disturbances are being resolved. Basically, the patient should be able to meet the following outcomes:

- Is comfortable with body image and able to use it effectively to meet human needs
- Is able to describe self positively
- Is able to meet realistic role expectations without undue anxiety and fatigue
- Is capable of interacting appropriately with environment while recognizing self to be a separate and distinct entity

See the accompanying Nursing Care Plan 42-1 on pages 1756–1758, for Ms. Motsky.

Focus on the Older Adult

PROMOTING SELF-ESTEEM IN OLDER ADULTS

Area of Concern	Nursing Strategies
Personal identity	• When an older adult's sense of self is threatened, assist the person to find meaning in the experience, to regain mastery to the extent that this is possible, and to evaluate realistically the adequacy of the person's coping strategy. • Teach older adults to identify and develop a game plan for confronting anxiety-producing situations. • Help to identify and secure intervention for treatable depressions. • Treat causes of self-identity disturbances such as pain, abusive living arrangements, and substance abuse.
Body image	• Notice and affirm positive physiologic characteristics of older adults. • Teach preventive self-care measures that reduce discomforting signs of aging (e.g., exercise, which maintains muscle mass and joint flexibility; proper nutrition; basic hygiene and skin care measures). • Explore new activities (including hobbies) that are within the changing physical capabilities of the older adult.
Self-Esteem	• Assist older adults to identify and use personal strengths. • Communicate that you value older adults simply for who they are (unconditional affirmation); know and use the name they prefer; ask them questions about their life, interests, or values. • Reinforce loving relationships, "It's obvious your son and grandchildren love you." "You must be a VIP—look at these flowers!"

	• When appropriate, use the expertise of older adults and ask their advice; let them know you value their life experiences. • Engage older adults in activities in which they can be successful. • Allow older adults to make tough decisions and confront challenging situations when appropriate; teach protective family members the value of older adults confronting situations that invite continued growth. • Empower older adults to meet their own needs; provide necessary knowledge, teach new behaviors, instill the belief that they "can manage."
Role performance	• Explore with older adults the many roles they have fulfilled throughout their lifetime; invite reminiscences. • Facilitate grieving over valued roles that can no longer be performed. • Remedy, whenever possible, factors that prevent older adults from engaging in valued roles. • Explore new roles.

REFLECTIVE PRACTICE LEADING TO PERSONAL LEARNING

Remember that the object of reflective practice is to look at an experience, understand it, and learn from it. As you begin to develop your expertise in identifying and responding to self-concept needs, reflect on your experiences—both successes and failures—in order to improve your practice. We all need to feel good about ourselves, but a healthy self-concept may take real work.

- Have you encountered patients or their family/caregivers whose self-concept and self-esteem needs are unmet? If you identified such needs, did you feel confident and comfortable responding to these needs?
- Have your care plans ever identified and addressed self-concept needs? Did your presence communicate respect and affirmation to each person you encountered today?
- Are you aware of any subtle messages you may be sending others that diminishes or violates their sense of worth? This may be a good time for some personal reflection about your own self-concept and self-esteem. Clinical practice challenges all of us, and some people are good at "pushing our buttons" and making us feel inadequate. How do you respond when this happens?

Perhaps the most important questions to reflect on are: Are your patients and their families/caregivers better for having had *you* share in the critical responsibility of partnering with them to nurture self-concept? Are your patients now receiving thoughtful, person-centered, prioritized, holistic, evidence-based treatment and care because of your efforts?"

Nursing Care Plan for Melissa Motsky 42-1

Melissa Motsky is a 31-year-old married woman, mother of three children (ages 12, 10, and 8 years), and junior-level nursing student. She works every other weekend as a nurse's aide. She has just received a letter from the nursing division head informing her that she is in academic jeopardy and will fail out of the program unless her grades improve. She presents this to her adviser.

After talking with Ms. Motsky, who calls herself "a failure" and who cries as she describes her situation at home, her faculty adviser suspects a serious self-esteem problem, and helps her to list factors contributing to her current sense of failure and low self-esteem. The following list is generated:

– Receives little understanding, affection, approval from husband. "I stay with him because of the kids. I started back to school because I had to get out of the house and want to make something of myself. He doesn't understand this."
+ "The children are very supportive but get impatient when I have to study and can't spend time with them."
– Feels a failure in all the roles that are important to her—wife, mother, and, now, student. "I jeopardized everything to go back to school—if I fail, it's all over for me. There just isn't enough time or energy to do anything well."
+ "They do love me at work, though, which makes me feel like nursing is what I should be doing."

– "I've always believed that hard work pays off, and that if you were faithful to your duty you'd be rewarded by the

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

good life—I'm beginning to doubt that. Maybe I'm a fool for trying so hard."

+ "I do still try to live according to my beliefs and feel okay about this. I treat others as I'd like to be treated."

– "I always believed I could do anything I put my heart and soul into. But I can't seem to change my marriage, and if I fail out of school, that will be the end of all my dreams."

Key indicators of low self-esteem that also surfaced in the interview include overeating (10-lb weight gain during the past year), difficulty sleeping, fatigue, new sensitivity to criticism, and expressions of feeling unloved, alone, and no longer able to manage. Personal strengths include history of "can do" mentality, high motivation to succeed, and past history of success as mother and nurse's aide.

Situational Low Self-Esteem related to decreased sense of significance, competence, virtue, and power; signs and symptoms: expressions of being a failure, powerlessness, fatigue, tears, weight gain, low academic performance (test grades 68, 74)

By this time next month, 11/2/25, the patient will demonstrate increased self-esteem by:

- Expressing positive statements about herself

Assist the patient to rediscover her "own" personal strengths: identify personal qualities and strengths that have pleased her in the past and explore why this has changed; recommend that she make at least one positive statement about herself each morning and evening.	Patients can lose touch with their strengths, especially when multiple stressors seem to create impossible demands.	11/3/25 Outcome partially met. Patient's statements are of the "This is good, *but*…" variety. "I think I'm doing better in school but I don't know if it will continue." *Recommendation:* Continue to identify and reinforce personal strengths. *C. Taylor, RN*
Consistently interact with the patient as if she had the power to weather the crisis successfully (i.e., "will" strength to her). Role-model positive self-concept behaviors.	Once the patient senses that an authority believes in her power and expects her to use it, she may internalize this knowledge and act on it.	

By this time next month, 11/2/25, the patient will demonstrate increased self-esteem by:

- Reporting ability to receive negative feedback without falling apart

Explore with the patient to what degree she allows the opinions of others to influence her self-concept.	Significance—sense of being loved and approved of by significant others—is a critical component of self-esteem.	11/3/25 Outcome partially met. Patient reports being able to handle everything except put-downs from her husband. *Recommendation:* Explore origin of power she has given to her husband to influence her sense of self and what she wants to do about this. *C. Taylor, RN*
Teach how self-concept filters life experiences; thus, if I feel that I am a failure, I may interpret the words and behaviors of others as confirming this, even though that was not their intention.	Principle of self-consistency: once I am down, I may reinforce this by distorting what I feel, hear, and experience.	
Explore with the patient ways she can enhance her self-concept independently of others (e.g., take time each day for herself). Encourage the patient to draw on personal strengths.	This facilitates internal locus of control versus external. Spending time on self communicates that self is valuable.	

Teach the patient how to analyze feedback constructively and respond appropriately; *cancel negative thinking*. For example, the patient receives care plan back with many corrections and the notation, "sloppy work." *Maladaptive response:* "She hates me. See, this proves I'll never be a good nurse. I wasted my time even doing this." *Adaptive response:* "I spent as much time as I had on this …now let me see what I did wrong. Maybe I should make an appointment with my instructor so she can show me how to improve."	It is important to break the cycle of negative thinking, which reinforces negative self-concept.	

By this time next month, 11/2/25, the patient will demonstrate increased self-esteem by:

- Getting a passing grade on her next quarterly examination

Explore study skills with the patient; recommend a study group.	Poor study skills may also be contributing to her low academic performance. A study group will meet both her social and academic needs.	11/3/25 Outcome met. Grade: 82 *C. Taylor, RN*
Discuss the importance of how she *perceives* present situation. If present failures are equated with *defeat,* she may be unable to mobilize her resources to succeed; if present failures represent *challenge,* it may call forth her best efforts and result in success.	The meaning given to present stressor can dramatically affect the patient's response to it and condition her for success or failure.	
Discuss the importance of breaking the cycle of failure leading to another failure.	If this short-term goal is met, it will set the stage for future successes and contribute to the patient's positive self-concept.	

By this time next month, 11/2/25, the patient will demonstrate increased self-esteem by:

- Verbalizing that the way she is living her life is okay

Assist the patient to examine her moral–ethical standards; explore sources of these standards and whether the patient feels comfortable with them.	Moral–ethical standards may be uncritically internalized and place the patient in conflict.	11/3/25 Outcome met. Patient stated: "I guess I'm living the best way I know how right now. If things are meant to be different, someone is going to have to show me how." *Recommendations:* Reinforce self-acceptance. *C. Taylor, RN*
Identify unrealistic standards; the patient may need "permission" to be human.	Unrealistic standards (perfectionism, conventionality) may constantly undermine the patient's self-esteem.	

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Refer for counseling, if appropriate.	Support groups on campus (counseling centers, ministries) may be able to meet the patient's needs.	

By this time next month, 11/2/25, the patient will demonstrate increased self-esteem by:

- Reporting two recent instances when personal power was effective in accomplishing desired goals

Identify and affirm the patient's use of personal power to accomplish goals.	A negative self-concept may deny or distort personal successes; outside intervention may be necessary to bring these to consciousness.	11/3/25 Outcome met … with difficulty. Needed considerable prompting to identify successful use of her personal power. Was ready to attribute passing grade to luck rather than her own efforts. *Recommendations:* Have patient make daily record of her use of personal power and results. *C. Taylor, RN*

10/2/25 Nursing
Melissa Motsky presented today after receiving academic jeopardy letter. She is strongly motivated to complete nursing program successfully and seems to have the ability to do this. Current multiple life stressors—lack of support from husband, need to mother three children (12, 10, 8), part-time nurse's aide job (necessary for financial reasons), and current academic jeopardy (test grades 68, 74)—are all contributing to her low self-esteem and overwhelming sense of being a failure. We together developed a care plan that it is hoped will help her to do better academically, as well as begin to feel better about herself. See attached. She will return 11/2/25 at 1000 for follow-up.

C. Taylor, RN

SOAP Format
10/2/25, 1230, Nursing
Academic jeopardy—Melissa Motsky
S: "I jeopardized everything to go back to school—if I fail, it's all over for me." Reports lack of support from husband, grief that she does not have enough time for children, failure of personal work ethic ("hard work pays off"), and sense of powerlessness.
O: Nursing II quarterly exam grades: 68, 74; weight gain of 10 lb during past year; facial and body expressions of fatigue, profuse tears
A: Low Self-Esteem related to decreased sense of significance, competence, virtue, and power
P: See attached care plan.

C. Taylor, RN

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

. Work through the Nursing Care Plan 42-1 for Melissa Motsky on pages 1756–1758 to help develop your clinical reasoning and clinical judgment skills.
. The personal strengths a person recognizes, develops, and uses are powerful but subjective determinants of self-concept. Identify the strengths that have been major determinants of your self-concept (e.g., power, intelligence, physical attractiveness, goodness, humor, "can do" attitude), and explore how these help you to succeed in nursing. Discuss with another student ways that nurses can assist patients to recognize, develop, and use personal strengths to cope better with the stress of injury and illness.
. Role-play with another student your responses to the following patients, then reverse roles. Reflect on the effects different types of nursing presence and response have on a patient's self-concept. Discuss the nursing responses that would be most helpful to patients at risk for self-concept disturbances.

- A man who was recently passed over for a promotion states, "I can't believe I've got to deal with this ulcer. It's just one more thing holding me back from succeeding in this business."
- An anorexic teenager tells you that she can't possibly eat the dinner you brought her, and states, "I can't do my usual workout in here, and look how fat I'm getting."
- A middle-aged patient confides, "I need to talk with someone about how it feels to be a woman trapped in a man's

body."

- A woman, after mastectomy, refuses to look at the incision site, and notes, "If I can't bring myself to look at this, how can I ever expect my husband to want me again?"
- Your patient confides that they lost their job during the pandemic, live in fear of being evicted because they can no longer pay the rent, knows their children are losing out because they have difficulty helping them with online classes, and hates that they can no longer afford the food and medicine they need. "What good am I?"
- A resident in a long-term care facility says, "Don't trouble yourself about me. I'm sure you have lots of people to take care of who are more deserving of your time and attention."

. What is your experience in relation to the self-concept and self-esteem of professional nurses? How does society affirm or challenge nursing's self-concept?

. You are the school nurse for a large middle school, and are approached by the parents of a 7th-grade transgender student whose sex assigned at birth was male, but who identifies as a female and wants permission to use the female bathroom. How do you respond? What informs your response?

. A young mother asks your opinions about parenting and the best way to develop their child's self-esteem. You know that "helicopter parenting"—a tendency to hover over children and swoop in to rescue them at the first sign of trouble—is producing higher rates of general anxiety in children. Children with overly controlling parents have higher levels of depression and report feeling less satisfied with family life. How do you respond to this mother, and what informs your response?

PRACTICING FOR NCLEX

. A nurse is performing a psychological assessment of an adolescent patient who has Down syndrome with mild intellectual disability. The patient tells the nurse, "I'm a good helper. I can carry things because I'm strong, but I'm not real smart, so I help with things I know how to do." What findings for self-concept and self-esteem would the nurse document for this patient?

a. Negative self-concept and low self-esteem
b. Negative self-concept and high self-esteem
c. Positive self-concept and fairly high self-esteem
d. Positive self-concept and low self-esteem

. A nurse asks a 25-year-old patient to describe themself with a list of 20 words. After 15 minutes, the patient listed, "25 years old, male, named Joe," then declared he could not think of anything else. What should the nurse document regarding this patient?

a. This patient presents with lack of self-esteem.
b. The patient does not possess self-knowledge.
c. This person has unrealistic expectations of themselves.
d. There is an inability to evaluate himself realistically.

. A nurse asks a patient who has few descriptors of themselves to list facts, traits, or qualities that they would like to apply to themselves. The patient quickly lists 25 traits of a successful person, stating, "My father is like this; I wish I were like him." How does the nurse best interpret the discrepancy between the patient's description of themselves as they are and how they would like to be seen?

a. The patient suffers from a negative self-concept.
b. This person demonstrates modesty (lack of conceit).
c. This individual has a disturbed body image.
d. The patient likely has a low self-esteem.

. A nurse is counseling a couple who have decided that the wife will provide financial support for the family while the husband attends pharmacy school. The husband plans to work 16 hours weekly, while attending school and states, "I was always an A student, but I might have to settle for Bs now because I don't want to neglect my family." How would the nurse document the husband's self-expectations?

a. Realistic and positively motivating their development
b. Unrealistic and negatively motivating their development
c. Unrealistic but positively motivating their development
d. Realistic but negatively motivating their development

. A school nurse is teaching parents how to foster a healthy development of self in their children. Which statement made by one of the parents requires further teaching?

a. "I love my child so much I 'hug him to death' every day."
b. "I think children need challenges, don't you?"
c. "My partner and I grew up in restrictive families; we want our children to be free to do whatever they want."

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

d. "We have different ideas about discipline, but we've continued our discussions so we can be consistent."

. A mother of an outspoken school-aged child tells the nurse: "I feel incompetent as a parent and have difficulty disciplining my child." What should be the nurse's first action when counseling this patient?

a. Recommending that she discipline her child more strictly and consistently
b. Making a "to-do" list for the child's father to allow her more time to focus on improving her parenting skills
c. Assisting the mother to identify both what she thinks is successful and what she can do to improve
d. Exploring how the child can improve their behavior and make the mother's role as a parent easier

. A nurse is conducting a parent workshop on how to build self-esteem in children. Which teaching points would the nurse include to help parents achieve this goal? Select all that apply.

a. Reinforce their child's positive qualities.
b. Overlook occasional negative behavior.
c. Ignore neutral behavior that is a matter of personal preference.
d. Listen and "fix things" for their children.
e. Describe the child's behavior and judge it.
f. Let their children practice skills and make it safe to fail.

. A nurse practicing in a health clinic assesses patient's self-concept during the patient intake. Which of these patients would the nurse identify has risk for problems related to self-concept?

a. Older adult scheduled for a hysterectomy next week
b. Young adult pastor whose vocal cords were paralyzed after a surgical procedure
c. Young accountant who survives a heart attack and near-death experience
d. Model who just learned that they have breast cancer
e. Adolescent recovering from a spinal cord injury who will be wheelchair "mobile"

. A patient who has been in the United States only 3 months has recently suffered the loss of partner and job. They state that nothing feels familiar—"I don't know who I am supposed to be here"—and says "I miss home terribly." For what alteration in self-concept is this patient most at risk?

a. Disturbed (or Risk for Disturbed) Personal Identity
b. Disturbed Body Image
c. Chronic (or Risk for Chronic) Low Self-Esteem or Situational (or Risk for Situational) Low Self-Esteem
d. Impaired Role Performance

. A sophomore in high school has missed a great deal of school due to treatment of leukemia. They stated they feel that they are falling behind in everything, and miss "hanging out at the mall" with friends most of all. What statement by the nurse is most appropriate?

a. "It sounds like you don't know who you are anymore…"
b. "Have the changes in your body since your diagnosis affected you?"
c. "How are you viewing yourself these days?"
d. "This must be difficult as adolescents' friends are very important to them."

. A college student visits the health clinic for a refill of a prescription for acne medication. In response to the nurse's question about how her semester is going the student bursts into tears and cries, "No one will ever ask me out on a date. I just want to be thin and pretty like the other girls." What response by the nurse could promote the student's examination of their self-esteem?

a. "You seem to have a negative body image and poor self-esteem."
b. "What are some things you'd like to change about your body."
c. "Most college students want to fit in; tell me what you enjoy doing."
d. "You are quite pretty and have a lovely figure."

. A young adult businessperson attends counseling, attempting to deal with a history of sexual abuse by their father. "I should feel satisfied with what I've achieved, but nothing I accomplish makes me feel good about myself…. I hate my father for making me feel like I'm no good. This is an awful way to live." What statement by the nurse would be most helpful?

a. "You've managed to overcome a lot since your childhood."
b. "Can you identify some positive attributes about yourself."
c. "Perhaps it's time to accept you're an adult and the abuse is in the past."
d. "What might make you feel more content? Go after it!"

. A patient is admitted through the emergency department with severe facial burns and cuts to the face after a car accident in in which their fiancé was the driver. Three weeks later, their fiancé has not yet contacted them. The patient

states that they are too tired to have visitors anyway and frequently lies with their eyes closed and head turned away. Based on this information, what action would the nurse take first?

a. Identify a disturbance in self-concept.
b. Question the patient about disturbances of body image.
c. Ask the patient how the accident has affected her.
d. Explain that the wounds are healing well, but she can consult a plastic surgeon after discharge if needed.

. A nurse is providing care for a patient with cancer who is approaching the end of life. Which nursing interventions will the nurse use to help the patient to maintain a positive sense of self? Select all that apply.

a. Making a point to address the patient by name upon entering the room
b. Avoiding fatiguing the patient by performing all procedures in silence
c. Performing care in a manner that respects the patient's privacy and preferences
d. Offering the patient a simple explanation before moving them in any way
e. Ignoring the patient's negative feelings since they are part of the grieving process
f. Avoiding conversing with the patient about their life, family, and occupation

. An older adult patient has a health problem of Disturbed Body Image documented on their care plan. The nurse discovers that patient feels they look old and feeble when ambulating with an assistive device often walking without it. The patient has fallen several times. What is an appropriate goal for this patient?

a. The patient will state the need to use the assistive device both inside and outside the house.
b. The patient will demonstrate proper use of the assistive device as observed by the nurse and physical therapist.
c. The patient will discuss their feelings about the device and compare that with the need for safety.
d. The patient will be given a wheelchair for mobility, as it is safer.

. A school nurse is meeting with the parent of a child who stated the child's other parent has been given a lengthy prison sentence. Which action by the nurse would be most helpful to mitigate an adverse child experience?

a. Assessing the student's grades and ability to complete class work
b. Suggesting a mentoring program for children of incarcerated parents
c. Asking the parent to tell you what happened
d. Suggesting the parent help the child identify their strengths

ANSWERS WITH RATIONALES

. **c.** The data point to the patient's positive self-concept ("I'm a good helper") and fairly high self-esteem (realizes their strengths and limitations). Stating, "But I'm not really smart" is likely accurate compared to non-disable peers and is not an indication of a negative self-concept.

. **b.** The patient's inability to list more than three items about themselves indicates deficient self-knowledge and lack of familiarity with their own qualities and traits. There is insufficient data to determine whether they lack self-esteem, have unrealistic self-expectations, or are unable to evaluate themselves.

. **d.** The nurse can obtain a quick indication of a patient's self-esteem by using a graphic description of self-esteem as the discrepancy between the "real self" (what we think we really are) and the "ideal self" (what we think we would like to be). The greater the discrepancy, the lower the self-esteem; the smaller the discrepancy, the higher the self-esteem.

. **a.** The patient's self-expectations are realistic, given their multiple commitments, and seem to be positively motivating their self-development.

. **c.** Each option with the exception of c correctly addresses some aspect of fostering healthy development in children. Because children need effective structure and development, giving them total freedom to do as they please may actually hinder their development.

. **c.** The nurse assesses the issue first, helping the mother identify what they believe is working and what is preventing them from being an effective parent. Next the nurse can explore solutions aimed at improving their parenting skills. Without assessment, there is no indication the child needs more strict discipline or assistance of the father. The child is not responsible for making the mother's parental role easier.

. **a, c, f.** The nurse should include the following teaching points for parents: (1) reinforce their child's positive qualities; (2) address negative qualities constructively; (3) ignore neutral behavior that is a matter of taste, preference, or personal style. Parents should allow children to be challenged or fail, rather than "fix things" for their children; avoid judgmental observations and let their child know what to expect, practice the necessary skills, be patient, and make it safe to fail.

. **b, c, d, e.** Based on the data, those who are at risk for negative self-concept include the pastor who will face challenges without his voice, the survivor of the near-death experience, and the model, whose work and livelihood depends on their physical appearance. The older adult would be least likely to experience body image or role performance

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

disturbance because they are beyond childbearing years, and the surgery should not impair their functional ability. The young clergyperson's inability to preach, the 32-year-old's massive myocardial infarction, and the model's breast resection have much greater potential to result in self-concept problems.

. **a.** An unfamiliar culture, coupled with traumatic life events such as loss of husband and job, result in this patient's total loss of their sense of self, supported by the statement: "I don't know who I am supposed to be here."

. **d.** Important roles for this adolescent include student and a friend; the illness is preventing them from doing either of these well, which reflects a disturbance in role performance. Stating that it sounds like you don't know who you are anymore is a question related to personal identity disturbance; asking about changes in the body would relate to disturbed body image; asking how are you viewing yourself these days relates to self-esteem disturbance.

. **b.** This patient is likely expressing concern with body image and self-esteem. The nurse seeks further information to support this, rather than suggesting the student has a negative body image or glossing over the student's concern and offering their opinion about the student's appearance or suggesting that their body needs changing. The nurse identifies the etiology of the student's concern, needing to fit in and be desired.

. **d.** This patient's self-concept disturbance is mainly one of devaluing themselves and thinking that they are no good. The nurse assists the patient in reframing their negative thoughts into positive thoughts.

. **c.** The nurse first assesses the patient's response to the accident before documenting a health problem and etiology. The nurse takes cues from the patient regarding their traumatic injuries, their fiancé's failure to contact them, and their withdrawal, which point to potential problems with both body image and self-esteem. The burn/trauma team would likely recommend plastic surgery, if indicated.

. **a, c, d.** Interventions to assist the patient to maintain a positive sense of self include addressing the patient by name when entering the room; performing care in a manner that respects the patient's privacy; offering simple explanations before moving the patient; acknowledging the patient's status, role, and individuality; and conversing with the patient about the patient's life experiences.

. **b.** The patient is demonstrating a maladaptive response. Patients who deny and avoid dealing with limitations or deformity, engage in self-destructive behavior, or fail to estimate relationship of body to environment are experiencing a disturbed self-concept. The patient will need to grieve the loss of mobility as they age as well as realize that safety is a priority to prevent injury. The other interventions focus on the negative without helping the patient reframe the situation or allowing the patient to discuss their feelings.

. **b.** Factors that can mitigate adverse child experiences include strengthening economic support to families; promoting social norms that protect against violence and adversity; and ensuring a strong start for children including support groups, mentoring, and teaching needed skills.

Stress and Adaptation

Mei Fu

Mei Fu is a 24-year-old graduate student. She is married, has two small children, and is taking courses toward a degree in physical therapy. Her husband is also a graduate student. Although she lived in China until 3 years ago, she speaks English well. After several months of headaches and diarrhea, Mei Fu made an appointment at the student health clinic.

Joan Rogerrio

Joan, a 48-year-old woman with a history of inflammatory bowel disease, comes to the outpatient clinic with reports of increasing episodes of diarrhea. She says, “I think my bowel disease is flaring up again.” Further assessment reveals she started a new job a month ago after being out of the workforce for the past 15 years. “Since the children are in school most of the day, my spouse and I decided it was time for me to go back to work to help out financially,” she says.

Christopher Weiss

Christopher, a nursing student, comes to the student health center saying that he feels sick. He states, "I'm supposed to start my critical care rotation tomorrow, and I'm terrified not only of the tubes and machines, but also of my instructor. I had her for my health assessment class, and it was really a disaster. I feel sick, and I am just shaking all over."

Learning Outcomes

After completing the chapter, you will be able to accomplish the following:

. Summarize the mechanisms involved in maintaining physiologic and psychological homeostasis.
. Explain the interdependent nature of stressors, stress, and adaptation.
. Differentiate the physical and emotional responses to stress, including local adaptation syndrome, general adaptation syndrome, mind–body interaction, anxiety, and coping and defense mechanisms.
. Discuss the effects of short- and long-term stress on basic human needs, health and illness, and the family.
. Compare and contrast developmental and situational stress, incorporating the concepts of physiologic and psychosocial stressors.
. Explain factors that cause stress in the nursing profession.
. Integrate knowledge of healthy lifestyle, support systems, stress management techniques, and crisis intervention into hospital- and community-based care.

stressor

Stress—a word taken from the term *distress*—is a part of life: Everyone feels stress at one time or another. Books and magazines are full of articles about stress that discuss everything from the stressful effects of performing your job to the positive (or negative) stress of holidays. Television and online advertisements for over-the-counter remedies promise fast relief from stress headaches and upset stomachs. Stress is blamed for obesity, drug and alcohol use, divorce, and

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

interpersonal violence. Feeling *stressed out* is common and taking *stress breaks* to do physical exercise is recommended in many work settings. Nursing emphasizes self-care, well-being, mental health, and building resilience (American Nurses Association, n.d.). With stress such a part of everyday life, it is easy to see that an additional health problem, such as an illness or injury, can increase the physical and psychological effects of stress. However, keep in mind that not all stress is negative. *Eustress* (Selye, 1976) is the term used for short-term stress that promotes positive emotional, intellectual, and physiologic adaptation and development.

The experience of stress and the responses to it are unique to each person. The process of responding to stress is constant and dynamic, and is essential to a person's physical, emotional, and social well-being. Stress is a major factor in health and illness. Nurses need to understand the concepts and levels of stress when providing nursing care to patients in all settings. Nurses themselves are subject to stress from the demands of their career and need to know healthy ways of responding (see the Reflective Practice display for an example).

BASIC CONCEPTS OF STRESS AND ADAPTATION

The basic concepts of stress and adaptation include stress, stressors, adaptation, and homeostasis.

Stress

Stress is a condition in which the human system responds to changes in its normal balanced state. Stress results from a change in a person's internal or external environment that is perceived as a challenge, a threat, or a danger. The major sources of stress in our society arise from interpersonal relationships and performance demands rather than from actual physical threats (Murdaugh et al., 2019). Stress is a part of the everyday human experience and our responses to stress shape who we are as people. Stress affects the whole person in all the human dimensions (physical, emotional, intellectual, social, spiritual) positively and negatively.

Think back to **Christopher Weiss,** the nursing student who reports feeling ill. He admitted feeling overwhelmed and extremely anxious about his upcoming critical care clinical rotation. His stressors included lack of confidence in manipulating the equipment and machines of the unit, and the demands that might be placed on him by the instructor. As a result, he exhibited physiologic responses to these stressors. These stressors could also affect his ability to function intellectually and socially.

The perception of stress and the responses to it are highly individualized. Responses vary not only from person to person, but also within a person depending on the specific circumstances, established coping mechanisms, available resources, and timing of the stress in that person's life. In addition, each person's perception of and responses to stress are influenced by that person's culture, family, history, and life experiences.

Stressors

A **stressor** is anything that is perceived as challenging, threatening, or demanding that triggers a stress reaction. Stressors may be internal (e.g., an illness, a hormonal change, or fear) or external (e.g., loud noise or cold temperature). As with stress, the perception and effects of the stressor are highly individualized. Stressors themselves are neither positive nor negative, but they can have positive or negative effects that may be short- or long-term.

QSEN Reflective Practice: Cultivating QSEN Competencies

CHALLENGE TO ETHICAL AND LEGAL SKILLS

I went to the student health center this afternoon because I was feeling sick. Tomorrow, I am supposed to begin my critical care rotation. My instructor is the same one that I had for health assessment, and that rotation was really a disaster. She has a reputation for being the hardest instructor in the school, and I struggled with the content that semester. I learned quite a bit but can't shake the nerves. I do not work in a hospital like many of my peers, and I'm pretty terrified of the tubes and machines that I'm going to be faced

with in the critical care unit. I'm still working on developing dexterity, and my hands shake when I get nervous—not a good combination. I actually tried to switch rotations and get on a less acute unit but had no luck. Now, I have to decide what to do tomorrow. I already feel a migraine starting.

Thinking Outside the Box: Possible Courses of Action

- Call in sick. Obviously, this can't be a long-term strategy.
- Grin and bear it. Just try to do my job and not stand out from my peers.
- Try to find a mentor in critical care to whom I can explain my fears and have the preceptor help me develop the skills I definitely need.
- Be honest with my instructor about my fears and the stress I am experiencing and ask for help.

Evaluating a Good Outcome: How Do I Define Success?

- I develop the technical and coping skills I need to effectively provide care in a high-tech environment.
- No patient is harmed because of my lack of skill and confidence.
- I learn to manage my stress and use it to my advantage.
- I pass this rotation with flying colors.

Personal Learning: Here's to the Future!

After some hard reflection (and the wise counsel of my mother), I decided I was giving my fear of this rotation (and instructor) way too much power over me. I realized that nursing would continue to put me in new and frightening situations, and I had better learn to deal with it now. Escape just couldn't be my modus operandi. I made it to clinical on time but was feeling jittery and queasy. Immediately after preconference, I literally grabbed my instructor and told her I had to talk to her before I began giving care. While she'll never be called warm and fuzzy, she surprised me by being understanding. Then she spent some extra time orienting me to the unit and helping me develop comfort with a lot of equipment I'd be using that day. I learned an important lesson in confronting fear and not letting it get the best of me. Hopefully, I can remember this the next time *flight* seems more attractive than *fight*!

Christopher Weiss, Georgetown University

QSEN SELF-REFLECTION ON QUALITY AND SAFETY COMPETENCIES DEVELOPING KNOWLEDGE, SKILLS, AND ATTITUDES FOR CONTINUOUS IMPROVEMENT

How do you think you would respond in a similar situation? Why? What does this tell you about yourself and about the adequacy of your skills for professional practice? Can you think of other ways to respond? What *knowledge, skills,* and *attitudes* do you need to develop to continuously improve quality and safety in situations like the one experienced by this student nurse?

Patient-Centered Care: Can you identify a beneficial aspect of the stress experienced by this student nurse? Did his handling of this stressful situation facilitate his ability to deliver effective care and treatment to his patients in a new environment? Did this student nurse's interaction with his instructor reinforce his commitment to treating patients with dignity and respect?

Teamwork and Collaboration/Quality Improvement: How important are effective communication skills when collaborating with team members? Did the acknowledgment of the student's personal stress and his decision to share these concerns with his instructor facilitate his understanding of the value of working in a nonpunitive environment? Explain the autonomic nervous system responses the nursing student was experiencing. How did the nursing student use task-oriented reactions and attack behavior? Propose some strategies that would be appropriate for him to use in the future to cope with stress and facilitate his role as an effective team member.

Safety/Evidence-Based Practice: Is there anything more the nursing student could have done to confront his fears, contribute to a safe patient care environment, and promote a positive outcome? Do you agree with his criteria to evaluate a successful outcome? Did the nursing student meet the criteria? What evidence in nursing literature provides guidance for managing stress in the work environment and finding effective methods to deal with it and care for yourself?

Informatics: Can you think of other ways to respond or to approach this situation? Do you think self-confidence gained from dealing effectively with stressful situations improves your ability to care for patients effectively and accurately document this care?

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Consider **Joan Rogerrio,** the middle-aged woman who is returning to the workforce and experiencing a recurrence of her inflammatory bowel disease. The decision to return to work was fostered by the family's financial need, which could also be a stressor for her. The stress of returning to work after a 15-year absence exerted a negative effect, resulting in frequent episodes of diarrhea.

Stressors can be physiologic or psychosocial. A physiologic stressor may cause psychosocial stress, and vice versa.

Physiologic Stressors

Physiologic stressors have both a specific effect and a general effect. The specific effect is an alteration of normal body structure and function. The general effect is the stress response. Primary physiologic stressors include chemical agents (drugs, poisons), physical agents (heat, cold, trauma), infectious agents (viruses, bacteria), nutritional imbalances, hypoxia, and genetic or immune disorders.

Psychosocial Stressors

There are an almost infinite variety of psychosocial stressors. They become such a part of our daily lives that we often minimize or overlook them. The environment, interpersonal relationships, or a life event can lead to the stress response if a person does not have the resources to adequately respond to the perceived or actual stressor. To illustrate the many types of psychosocial stressors, consider those listed in Box 43-1. Psychosocial stressors include both real and perceived threats. The person's responses are continuous and include individualized coping mechanisms for responding to anxiety, guilt, fear, frustration, and loss. Coping mechanisms serve to maintain psychological homeostasis.

Box 43-1 Examples of Psychosocial Stressors

- Accidents, which cause stress for the victim, the person who caused the accident, and the families of both
- Stressful or traumatic experiences of family members and friends
- Horrors of history, such as Nazi concentration camps, the dropping of the atomic bomb on Hiroshima, the September 11, 2001 or Orlando Pulse nightclub (2016) terrorist attacks, any of the school shootings of 2018 (e.g., Parkland, FL), or the murder of George Floyd in May 2020 that fueled the Black Lives Matter movement
- Fear of aggression or mutilation, such as muggings, rape, shootings, and terrorism
- Events of history that are brought into our homes through television and the Internet, such as wars, earthquakes, violence in schools, and civil unrest
- Rapid changes in our world and the way we live, including changes in economic and political structures, rapid advances in technology, and shifting values and priorities
- The inherent stressors, social isolation, political divides, change in work-life separation, and public health crisis brought about by the COVID-19 pandemic that began in 2020

Adaptation

When a person is in a threatening or otherwise stressful situation, immediate responses occur. Those responses, which are often involuntary, are called coping responses. The change that takes place as a result of the response to a stressor is referred to as **adaptation**. Adaptation is, to some degree, an ongoing process as a person strives to maintain balance in the internal and external environments (Fig. 43-1). Adaptation also occurs in families and groups. Adaptation is necessary for maintaining normal growth and development, tolerating changing situations, and responding to physical and emotional stressors.

Homeostasis

Our bodies are always interacting with a constantly changing environment, including the external environment that surrounds our bodies and the internal environment that includes the mechanisms that regulate body functions and the

fluids that surround body cells. To maintain health, the body's internal environment must remain in a balanced state. Various physiologic mechanisms within the body respond to internal changes to maintain **homeostasis**, a relative constancy in the internal environment.

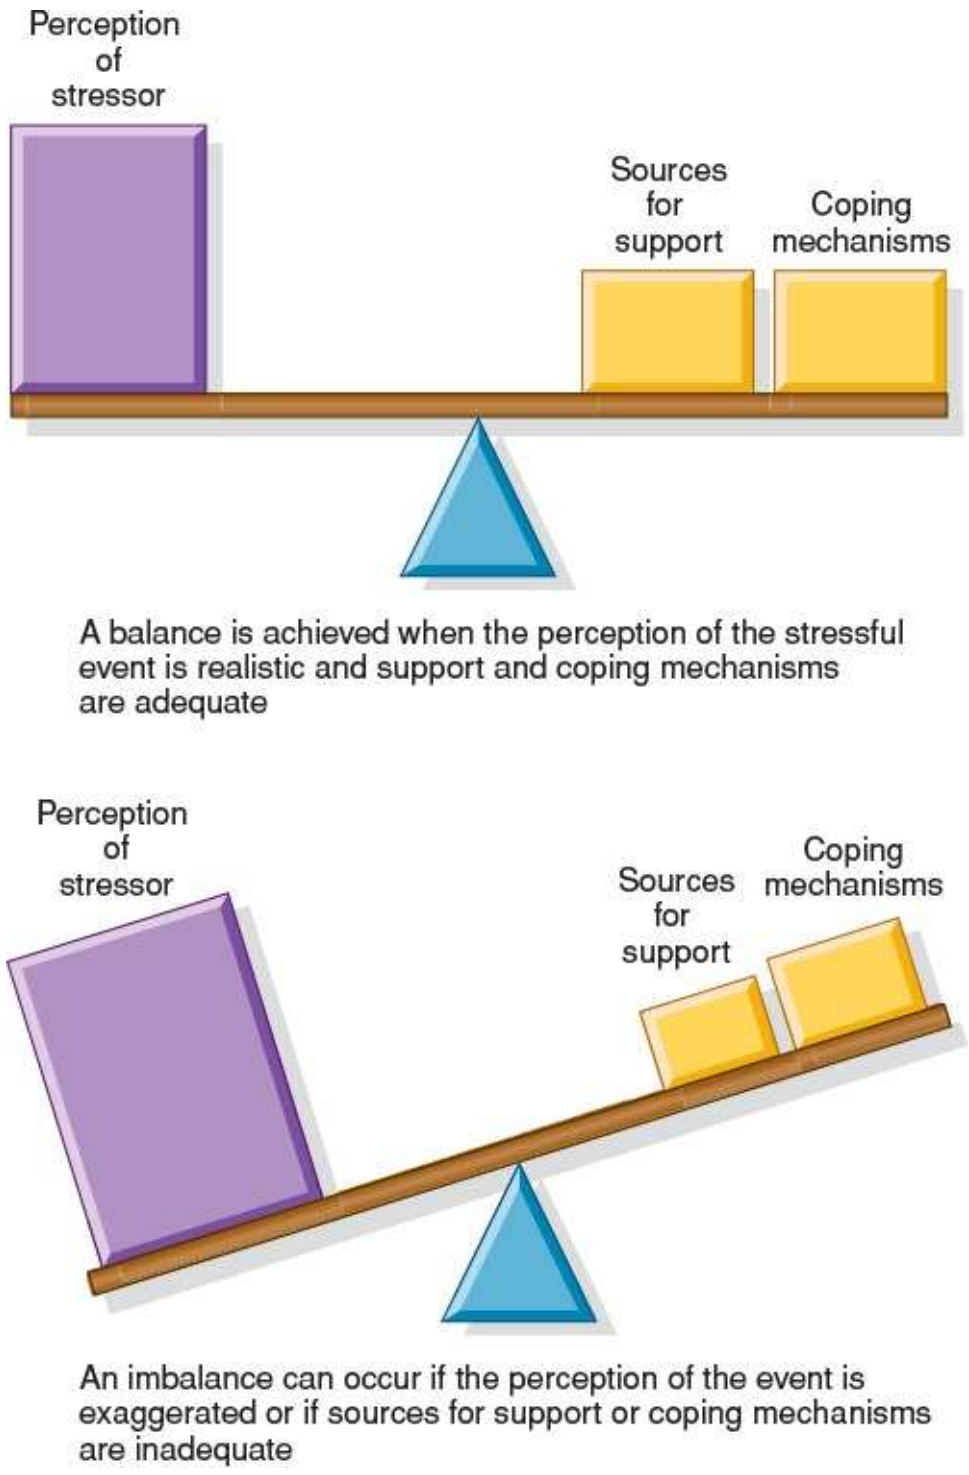

FIGURE 43-1. A realistic perception of a stressful event, sources for emotional support, and appropriate coping mechanisms are components of a system of balances during stress.

Throughout history, people have believed that health is the result of a balanced state. Some of the most important people in medical history, including Hippocrates (modern medicine) and Claude Bernard (homeostasis physiology), believed in and wrote about this balanced state. Originally, the focus was on life processes that occur within the body such as heart rate, blood pressure, and water balance. The concept of homeostasis has been expanded to include both physiologic and psychological balance.

MAINTENANCE OF PHYSIOLOGIC AND PSYCHOLOGICAL HOMEOSTASIS

The effects of physiologic and psychological stress are interrelated, as are the mechanisms that are consciously or unconsciously used to maintain homeostasis in response to stress. For example, the mechanisms described later, including the general adaptation syndrome (GAS) and mind–body interaction, are physiologic responses to either physical or emotional stressors.

Physiologic Homeostasis

The autonomic nervous system and the endocrine system primarily control homeostatic mechanisms. The respiratory, cardiovascular, gastrointestinal, and renal systems are involved to a lesser degree. These mechanisms are self-regulating, organized, and coordinated; they occur without conscious thought, and defend against change to the body's internal environment. On a simple level, these self-regulating mechanisms are like a thermostat regulating a furnace. When the temperature in a house falls below the preset temperature on the thermostat, the thermostat turns on the furnace, which heats the house to the desired temperature and then shuts off. This is a classic example of a negative feedback system, which is the primary means by which homeostasis is maintained (Norris, 2020).

The regulatory mechanisms of the body are reacting constantly to internal changes to maintain homeostasis and

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

health. The homeostatic mechanisms of the body systems are summarized in Table 43-1 on page 1768. These mechanisms explain the consequences of both short- and long-term stress, which can threaten physiologic homeostasis and result in illness. In the 1980s, some investigators began using the term **allostasis** to describe this process of achieving stability or homeostasis through physiologic or behavioral change. The cumulative negative effects of these physical responses to prolonged environmental and psychosocial stressors are referred to as an *allostatic load*. This represents the consequences of ongoing stress on the body with its resultant risks for a variety of diseases (McEwen & Stellar, 1993; Norris, 2020). Box 43-2 provides examples of illnesses known to be associated with stress.

Box 43-2 Examples of Physical Illnesses Associated With Stress

Autoimmune Disorders

Graves disease (hyperthyroidism)
Myasthenia gravis
Psoriasis
Rheumatoid arthritis
Systemic lupus erythematosus (SLE)
Ulcerative colitis

Cardiovascular and Hematologic Disorders

Coronary artery disease
Hypertension
Sickle cell disease

Gastrointestinal Disorders

Constipation
Diarrhea
Esophageal reflux

Respiratory Disorders

Asthma

Local Adaptation Syndrome

The **local adaptation syndrome (LAS)** is a localized response of the body to stress. It involves only a specific body part (such as a tissue or organ) instead of the whole body. The stress precipitating the LAS may be traumatic or pathologic. LAS is a primarily homeostatic, short-term adaptive response. Although the body has many localized stress responses, the two most common responses that influence nursing care are the reflex pain response and the inflammatory response.

REFLEX PAIN RESPONSE

The **reflex pain response** is a response of the central nervous system to pain. It is rapid and automatic, serving as a protective mechanism to prevent injury. The reflex depends on an intact, functioning neurologic reflex arc and involves both sensory and motor neurons. For example, if you step into a bathtub of dangerously hot water, sensors in your skin detect the heat and immediately send a message to the spinal cord. A message is then sent to a motor nerve, which activates the muscles in your leg to pull back your foot. All of this happens before you consciously realize that the water is too hot to be safe. The pain response is discussed in Chapter 36.

INFLAMMATORY RESPONSE

The **inflammatory response** is a local response to injury or infection. It serves to localize and prevent the spread of infection and promote wound healing. When you cut your finger, for example, you often develop the symptoms of the inflammatory response: pain, swelling, heat, redness, and changes in function. The inflammatory response is discussed in Chapter 33.

Table 43-1 Homeostatic Regulators of the Body

SYSTEM	ACTION	EFFECT
Autonomic Nervous System *Parasympathetic*—Functions under normal conditions and at rest (cranial and sacral nerves)		
	Regulates heart rate	Slows rate

	Stimulates secretion of digestive juices and digestive tract smooth muscle Stimulates insulin secretion	Improves digestion, increases peristalsis Increases uptake of glucose by cells
Sympathetic—Functions under stress conditions to bring about the fight-or-flight response		
	Stimulates heart rate and force Dilates skeletal muscle blood vessels Dilates blood vessels to the brain Stimulates release of glycogen stores	Increases rate, strengthens contractions, increases cardiac output Increases muscle strength Increases mental alertness Increases blood glucose levels
Endocrine System		
Pituitary	Secretes hormones:	
	• Adrenocorticotropic hormone (ACTH)	Stimulates the adrenal cortex
	• Thyroid-stimulating hormone (TSH)	Stimulates the thyroid
Adrenals	Medulla produces epinephrine and norepinephrine Cortex secretes mineralocorticoids, glucocorticoids, and androgens	Prepares the person for emergencies; supports the sympathetic system Mineralocorticoid aldosterone regulates fluid and electrolytes Glucocorticoids (cortisol) raise glucose levels (for energy) and increase resistance to physical stress Androgens control the development and maintenance of male characteristics and are the primary precursor of natural estrogens
Thyroid	Secretes thyroid hormone and calcitonin	Regulates metabolic rate and growth
Other		
Cardiovascular	Serves as transport system and pump	Provides oxygen and nutrients and removes carbon dioxide and wastes from cells
Renal	Filters, excretes, and reabsorbs metabolic products and water	Maintains fluid, electrolyte, and acid–base balance
Respiratory	Regulates inhalation of oxygen and exhalation of carbon dioxide	Necessary for metabolism; helps maintain acid–base balance
Gastrointestinal	Digests and metabolizes food and fluids Eliminates waste products	Energy sources; maintains fluids and electrolytes

General Adaptation Syndrome

The **general adaptation syndrome (GAS)** is a biochemical model of stress developed by Selye (1976). The GAS describes the body's general response to stress, a concept that impacts all facets of nursing care. The three stages in the GAS are alarm reaction, stage of resistance, and stage of exhaustion (Fig. 43-2). Although the alarm stage is short term (minutes to hours), the length of the resistance and exhaustion stages varies greatly, depending on such variables as the severity and duration of the stressor, the person's previous health and coping mechanisms, and the immediacy and effectiveness of health care interventions.

The GAS is a physiologic response to stress, but it is important to remember that the response results from either physical or emotional stressors, and the stages occur with either physical or psychological damage to the person. Obvious examples are seen in patients with severe injury or an illness, but GAS is also a factor in mental illness, social isolation, and loss of (or lack of) human relationships.

ALARM REACTION

Alarm is initiated when a person perceives a specific stressor and various defense mechanisms are activated. The perception of threat may be conscious or unconscious. The hypothalamic–pituitary–adrenal (HPA) axis controls the neuroendocrine response, and hormone and catecholamine levels rise to prepare the body to react. The sympathetic nervous system initiates the **fight-or-flight response**, preparing the body to either fight off the stressor or to run away from it (usually not literally in the modern world). This phase of the alarm reaction, called the shock phase, is

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

characterized by an increase in energy levels, oxygen intake, cardiac output, blood pressure, and mental alertness. (If you recall the last time you almost had a car crash, you can easily identify these body reactions!) During the second phase of the alarm reaction, countershock, there is a reversal of body changes.

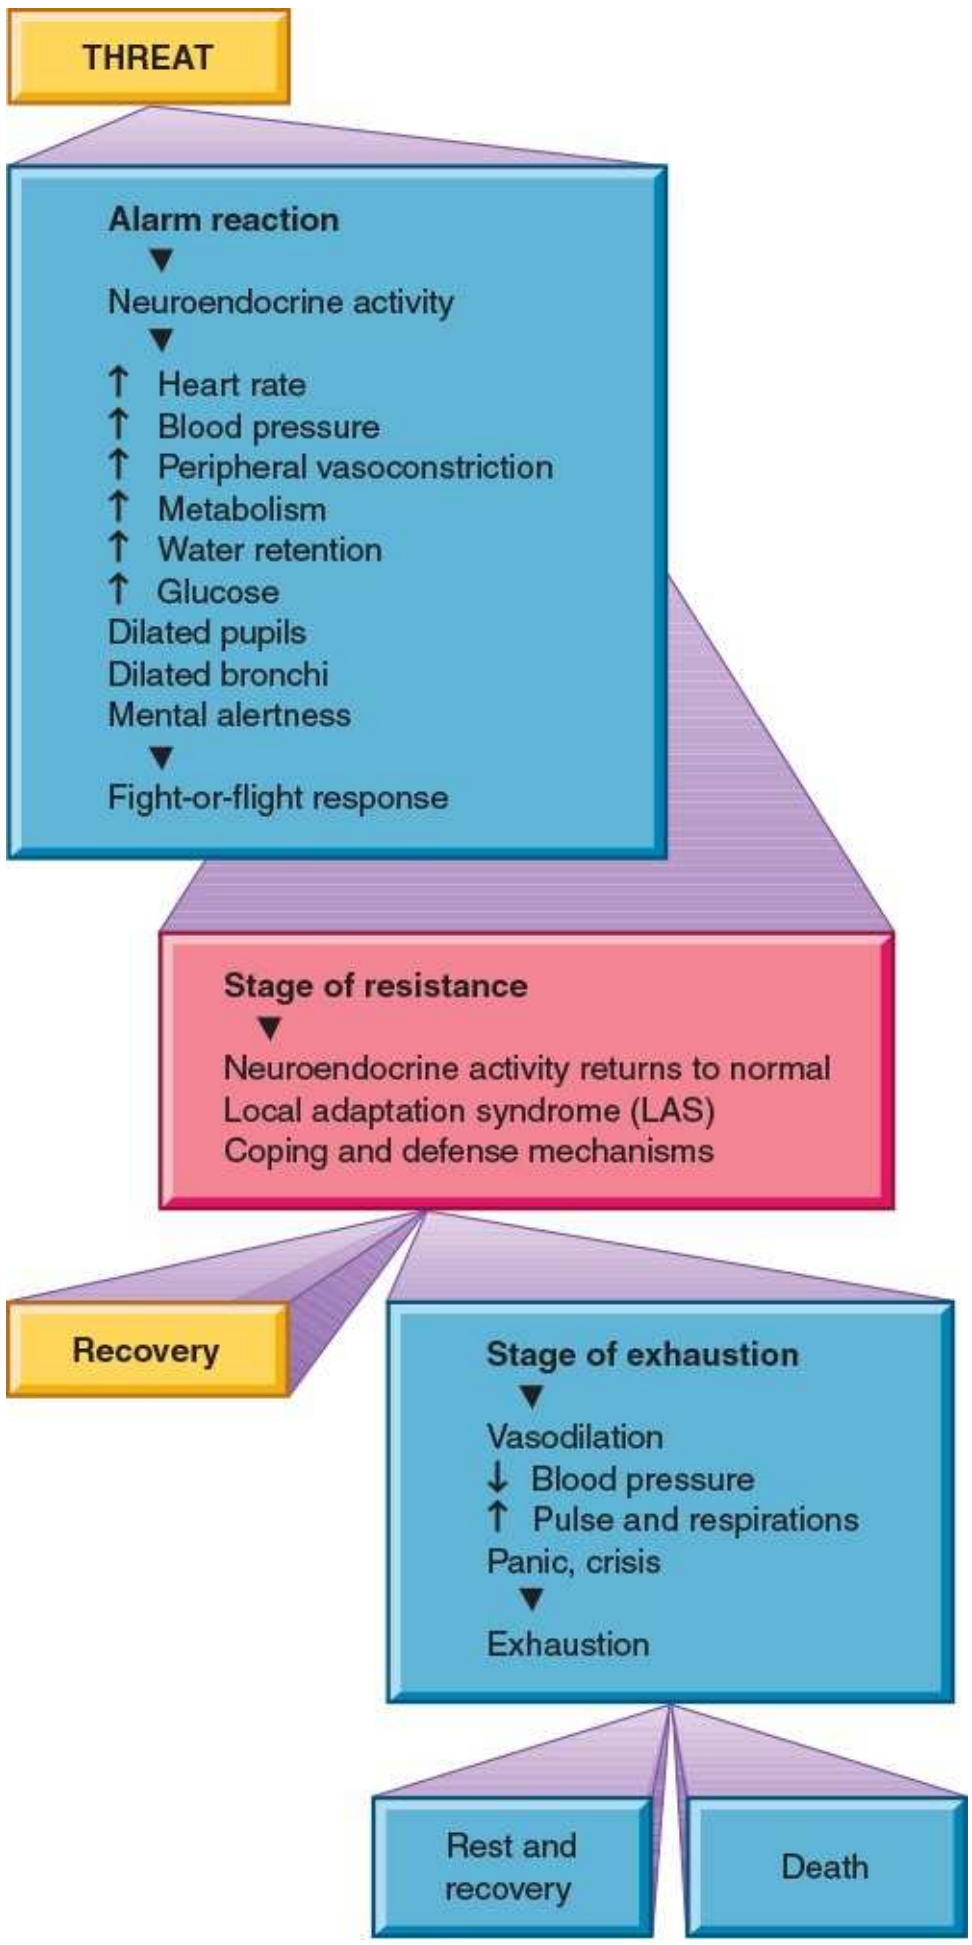

FIGURE 43-2. The general adaptation syndrome (general response to stress).

STAGE OF RESISTANCE

Having perceived the threat and mobilized its resources, the body now attempts to adapt to the stressor. Vital signs, hormone levels, and energy production return to normal. If the stress can be managed or confined to a small area (LAS), the body regains homeostasis. If the stressor is prolonged or strong enough to overwhelm the body's ability to defend itself (e.g., severe injury and bleeding or a major illness such as cancer or a heart attack), the adaptive mechanisms become exhausted.

STAGE OF EXHAUSTION

Exhaustion results when the adaptive mechanisms can no longer provide defense. This depletion of resources results in damage to the body in the form of *wear and tear* or systemic damage (Norris, 2020). Without defense against the stressor, the body may either rest and mobilize its defenses to return to normal or reach total exhaustion and die.

Psychological Homeostasis

To maintain mental well-being, humans also must maintain psychological homeostasis. As discussed in Chapter 4, every person needs to feel loved and a sense of belonging, to feel safe and secure, and to have self-esteem. When these needs are not met or a threat to need fulfillment occurs, homeostatic measures in the form of coping or defense mechanisms help return the person to emotional balance.

Individuals frequently encounter physical, psychological, and social changes in their internal and external environments. A person's perception of these changes may be conscious or unconscious. If the person has the necessary resources, adaptation takes place and balance is maintained. If the resources cannot reestablish balance, a state of stress results. The person's responses and the degree of stress depend in part on the nature, intensity, timing, number, and duration of stressors. Adaptation to stress also depends on a person's age, developmental level, past experiences, support systems, and coping mechanisms (see Box 43-3 for sources of stress with aging). Adaptive responses include the mind–body interaction, anxiety, and coping or defense mechanisms.

Mind–Body Interaction

Consider the following examples of mind–body interaction:

Box 43-3 Sources of Stress With Aging

Stress, with resultant anxiety, is a known risk for individuals in the older population. As the number of older adults increases in the population, anxiety is now, and increasingly will be, a significant problem. Not all older adults will experience stress to the point of anxiety, but anxiety should be kept in mind as a possible problem when providing nursing care for older adults in the following situations:

- Invasive or health-related tests or examinations
- Surgical procedures
- Diagnosis of chronic illnesses, including diabetes, cancer, and cardiovascular diseases
- Declining physical and/or mental capabilities
- Retirement
- Loss of spouse or significant other
- Increased social isolation
- Chronic pain
- Alcohol abuse
- Loss of independence in living arrangements, driving, or activities of daily living

- Tomorrow, you are scheduled to take a final examination, and you must earn a passing score to pass the course and remain in the nursing program. After being awake most of the night, you cannot swallow any food at breakfast, you have a rapid heartbeat, you are filled with feelings of apprehension, and you have diarrhea.
- Since his wife was killed in a car crash, Tom Green has been the sole support of his 4-year-old son, who is developmentally disabled and hyperactive. Tom has been coming to the neighborhood health clinic with increasing frequency over the past 5 months, reporting weight loss, headaches, and stomach pain.

These examples illustrate the relationship between psychological stressors and the physiologic stress response (the GAS). In the first example, as you begin the test and discover that you know most of the answers, your stress decreases and your symptoms disappear rapidly. Tom's stress, however, is always present and is long term, increasing his risk for developing an illness.

Remember **Christopher Weiss,** the nursing student who said he felt he was getting sick from fears about his upcoming clinical rotation in the critical care unit and anticipation of having a strict instructor. As a result of his anticipated fears and lack of confidence, he physiologically responded to the stressors by feeling sick.

What causes this link between psychological stressors and the physiologic stress response? Although the exact cause

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

is not well understood, it is thought that humans react to threats of danger as if they were physiologic threats. A person perceives the threat on an emotional level, and the body prepares itself either to resist the danger or to run away from it (the fight-or-flight response); see Figure 43-3.

Each person reacts in their own way to prolonged stress. Some may develop chronic diarrhea, while others may develop nausea or heart palpitations. Such illnesses are real and are called **psychosomatic disorders** because the physiologic alterations are thought to be at least partially caused by psychological influences.

Another component of mind–body interaction is the effect of life changes on a person. Researchers have found that the number of changes a person has in life (both positive and negative) can be correlated with illness. A life change is defined as an event in a person's life that requires energy for adaptation. When energy is expended to adapt to the event, the person's resistance to illness is lowered. For example, although a holiday celebration with family and friends is considered a positive event in a person's life, factors including the time necessary to prepare for the party, worrying about how everyone will get along, and trying to decide how much money to spend can generate stress.

Anxiety

The most common human response to stress is anxiety. **Anxiety** is a vague, uneasy feeling of discomfort or dread, the source of which is often unknown or nonspecific. It is also a feeling of apprehension caused by anticipating a perceived danger. Anxiety is experienced at some time by all people. Left unchecked, anxiety can affect person physically and emotionally, alter their self-perceptions, and impact on social relationships (American Psychological Association [APA], 2022). In contrast, **fear** is a feeling of dread in response to a known threat.

Anxiety is often present before new experiences, such as starting college or beginning a new job, which may be perceived as a threat to a person's identity and self-esteem. The four levels of anxiety are mild, moderate, severe, and panic; each level has different effects. At a mild level, anxiety can have a positive effect; for example, mild anxiety about an upcoming examination can motivate a student to do the required reading and review. Anxiety beyond that level is generally negative and has unpleasant effects. In an attempt to neutralize, deny, or counteract the anxiety, the person develops individual patterns of coping.

MILD ANXIETY

Mild anxiety is present in day-to-day living. It increases alertness and perceptual fields (e.g., vision and hearing) and motivates learning and growth. Although mild anxiety may interfere with sleep, it also facilitates problem solving. Mild anxiety is often manifested by restlessness and increased questioning.

MODERATE ANXIETY

Moderate anxiety narrows a person's perceptual fields so that the focus is on immediate concerns, with inattention to other communications and details. Moderate anxiety is manifested by a quavering voice, tremors, increased muscle tension, a report of "butterflies in the stomach," and slight increases in respirations and pulse.

SEVERE ANXIETY

Severe anxiety creates a very narrow focus on specific details, causing all behavior to be geared toward getting relief. The person has impaired learning ability and is easily distracted. Severe anxiety is characterized by extreme fear of a danger that is not real, emotional distress that interferes with everyday life, and avoidance of situations that cause anxiety. It is manifested by difficulty communicating verbally, increased motor activity, a fearful facial expression, headache, nausea, dizziness, tachycardia, and hyperventilation. At this point, anxiety is no longer functioning as a signal for danger or motivation for a needed change, but instead results in maladaptive behaviors and emotional instability that signal the presence of an anxiety disorder.

PANIC

Panic causes the person to lose control and experience dread and terror. The resulting disorganized state is characterized by increased physical activity, distorted perception of events, and loss of rational thought. Panic is manifested by difficulty communicating verbally, agitation, trembling, poor motor control, sensory changes, sweating, tachycardia, hyperventilation, dyspnea, palpitations, a choking sensation, and sensations of chest pain or pressure. The person is unable to learn, concentrates only on the present situation, and often experiences feelings of impending doom. This level of anxiety can lead to exhaustion and death.

FIGURE 43-3. The effects of stress. (Courtesy of the American Institute of Stress. https://www.stress.org/the-effects-of-stress)

ANXIETY DISORDERS

Anxiety disorders are a group of conditions in which excessive anxiety is the key feature. This type of anxiety is persistent and affects responses from a cognitive, behavioral, emotional, and physiologic perspective (Videbeck, 2019). Anxiety disorders include panic disorder, generalized anxiety disorder (GAD), phobias (agoraphobia, social phobia, specific phobia), separation anxiety disorder, posttraumatic stress disorder (PTSD), and obsessive-compulsive disorder (OCD; Kessler et al., 2012). During 2019, 9.5% of adult experienced mild anxiety, 3.4% experienced moderate anxiety, and 2.7% experienced severe anxiety in the past 2 weeks. Females were more likely to report anxiety and those ages 18 to 29 years were most affected (Center for Disease Control and Prevention [CDC], 2020b). The prevalence of mental health disorders, especially depression and anxiety, surged nationwide in response to the pandemic. Between January 2020 and September 2020, anxiety screens increased by 634% (Mental Health America, 2020).

Coping Mechanisms

Anxiety is often managed without conscious thought by **coping mechanisms**, which are behaviors used to decrease stress and anxiety. Many coping behaviors are learned, based on a person's family, past experiences, and sociocultural influences and expectations. As illustrated in the list that follows, coping behaviors may be positive or negative in terms

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

of how they affect health. Typical coping behaviors include the following:

- Crying, laughing, sleeping, cursing
- Physical activity, exercise
- Taking a deep breath, using practiced mindfulness/centering exercises
- Verbally debriefing with another person, journaling
- Engage in an enjoyable activity as a distraction
- Smoking, drinking
- Lack of eye contact, ignoring the stressor, withdrawal
- Limiting relationships to those with similar values and interests

Moderate, severe, and panic levels of anxiety are greater threats and involve more complex coping mechanisms as the person strives to reduce the stress and anxiety. Coping mechanisms often used at higher levels of anxiety are categorized as task-oriented reactions. Task-oriented reactions involve consciously thinking about the stress situation and then acting to solve problems, resolve conflicts, or satisfy needs. These reactions include attack behavior, withdrawal behavior, and compromise behavior.

Attack behavior occurs when a person attempts to overcome obstacles to satisfy a need; it may be constructive, with assertive problem solving, or destructive, with feelings and actions of aggression and hostility. Withdrawal behavior involves physical withdrawal from the threat, or emotional reactions such as admitting defeat, becoming apathetic, or feeling guilty and isolated. Compromise behavior is usually constructive, often involving the substitution of goals or negotiation to partially fulfill needs.

Defense Mechanisms

Other unconscious reactions to stressors, called **defense mechanisms**, often occur. These mechanisms protect a person's self-esteem and are useful in mild to moderate anxiety. When extreme, however, they distort reality and create problems with relationships. At that point, the mechanisms become maladaptive instead of adaptive. Some common defense mechanisms are summarized in Table 43-2.

EFFECTS OF STRESS

Physiologic and psychological stress affects all dimensions of a person. Stress strongly influences how a person attains basic human needs, it is a factor in health and illness, and it is a component in family reactions to illness. Both long-term stress and crisis situations may seriously affect physical and emotional health.

Stress and Basic Human Needs

The drive to meet basic human needs (described in Chapter 4) and address stress are universal human experiences. Meeting basic needs and adapting to stress requires energy and intentional action. As a person strives to meet basic human needs at each level, stress can be either a stimulus or a barrier. Actions to achieve balance are individualized and depend on the person's sociocultural background, priorities, and past experiences. In all people, the failure to meet needs results in an imbalance in homeostatic mechanisms and, eventually, illness (Box 43-4).

Box 43-4 Effects of Stress on Basic Human Needs

Physiologic Needs

Change in appetite, activity, or sleep
Change in elimination patterns
Increased pulse, respirations, blood pressure

Safety and Security

Feels threatened or nervous
Uses ineffective coping mechanisms
Is inattentive

Love and Belonging

Is withdrawn and isolated
Blames others for own faults
Demonstrates aggressive behaviors
Becomes overly dependent on others

Self-Esteem

Becomes a workaholic
Exhibits attention-seeking behaviors

Self-Actualization

Refuses to accept reality
Centers on own problems
Demonstrates lack of control

Stress in Health and Illness

The health–illness continuum (described in Chapter 3) is affected by stress. Health and homeostatic balance are at one extreme of the continuum; exhaustion and death are at the other extreme.

Table 43-2 Commonly Occurring Defense Mechanisms

DEFENSE MECHANISM	CAUSES	EXAMPLE
Compensation	A person attempts to overcome a perceived weakness by emphasizing a more desirable trait or overachieving in a more comfortable area.	A student who has difficulty with academics may excel in sports.
Denial	A person refuses to acknowledge the presence of a condition that is disturbing.	Despite finding a lump in her breast, a woman does not seek medical treatment.
Displacement	A person transfers (displaces) an emotional reaction from one object or person to another object or person.	An employee who is angry with a coworker kicks a chair.
Dissociation	A person subconsciously protects themself from the memories of a horrific or painful event by allowing the mind to forget the incident.	An adult cannot recall childhood memories surrounding the traumatic death of a sibling.
Introjection	A person incorporates qualities or values of another person into their own ego structure. This mechanism is important in the formation of conscience during childhood.	An older sibling tells his preschool sister not to talk to strangers, expressing his parents' values to his younger sister.
Projection	A person attributes thoughts or impulses to someone else.	A person who denies any sexual feelings for a coworker accuses them of sexual harassment.
Rationalization	A person tries to give a logical or socially acceptable explanation for questionable behavior ("behavior justification").	A patient who forgot to keep a health care appointment says, "If patients didn't have to wait 3 months to get an appointment, they wouldn't forget them."
Reaction formation	A person develops conscious attitudes and behavior patterns that are opposite to what they would really like to do.	A married woman is attracted to her husband's best friend but is constantly rude to him.
Regression	A person returns to an earlier method of behaving.	Children may regress to soiling diapers or demanding a bottle when they are ill.
Repression	A person voluntarily excludes an anxiety-producing event from conscious awareness.	A father may not remember shaking his crying baby.
Sublimation	A person substitutes a socially acceptable goal for one whose normal channel of expression is blocked.	A person who is aggressive toward others may become a star football player.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Undoing	A person uses an act or communication to negate a previous act or communication.	A husband who was physically abusive to his wife may bring her an expensive present the next day.

Stress in a healthy person may promote health and prevent illness. For example, the fear of developing lung cancer may motivate a person to stop smoking, or anxiety about baby care may prompt prospective parents to attend prenatal classes and read childcare books. Stressors in health also facilitate normal growth and development, provide the stimulus for learning constructive adaptive behaviors, stimulate problem-solving abilities, encourage social relationships, and help develop spiritual strength and resilience.

The effects of stress on a sick or injured person are, in contrast, usually negative. Stress can make illness worse, and illness can cause stress. The presence of an illness or a disability demands new coping skills at a time when homeostasis is challenged. People who enter health care settings as patients are also subjected to situational stressors.

Remember **Joan Rogerrio,** the woman experiencing an exacerbation of her bowel disease. The negative effects of stress exacerbated her illness. As a result, Joan needs to develop new coping skills to deal with the demands of working to minimize the negative effects of this stressor on her illness.

Adaptation to acute and chronic illness or to traumatic injury involves two sets of adaptive tasks:

. General tasks (as in the case of any situational stress) involve maintaining self-esteem and personal relationships while preparing for an uncertain future.
. Illness-related tasks include such stressors as losing independence and control, managing pain and disability, and carrying out the prescribed medical regimen.

Every situation is different, and each person perceives and reacts to stressors in an individual manner. There is no one *best* way to cope with a given situation. Nursing considerations include the person's major concern, specific illness, sociocultural background, and available resources. For example, an older patient may be anxious about the cost of treatment for a hip fracture, whereas another patient with the same injury may be seriously worried about the care of their cats while she is in the hospital. As another example, Kristin and Jane have both entered the hospital for treatment of breast cancer. Kristin is worried about possible disfigurement and death, but she believes that with the help of surgery and chemotherapy, she can overcome the cancer. Jane, on the other hand, comes from a community that has strong fundamental religious beliefs. She believes that the cancer is a punishment from God and refuses treatment, even though she fears death.

Long-Term Stress

Long-term stress poses a serious threat to physical and emotional health. As the duration, intensity, or number of stressors increases, a person's ability to adapt is lessened. The failure of adaptive mechanisms is also influenced by a person's state of health and past experiences with stress. In 2020, with the pandemic continuing well past initial predictions, 77% of adults reported the *future of the nation* as a significant source of stress, and almost 65% specified the *current amount of uncertainty* as the primary source of stress. Health care (66%), mass shootings (62%), and climate change (55%) represent the top three, specific, societal stressors identified. The prolonged state of stress experienced by the world constitutes a mental health crisis that could result in long-lasting health and societal issues (APA, 2020).

Long-term stress affects physical status, increasing the risk for disease or injury. Recovery and return to normal function are also compromised. High levels of ongoing stress are associated with multiple health disorders (see Box 43-2 on page 1767). Alcoholism and drug abuse, depression, suicide, accidents, and eating disorders have also been associated with chronic stress (Norris, 2020). It is believed that these diseases are the result of various factors, including the effects of the fight-or-flight response, eating patterns, lifestyle, and coping mechanisms. Stress alone does not cause autoimmune diseases such as rheumatoid arthritis, but it is believed to contribute to the progression of these diseases. Researchers have confirmed that chronic stress affects the ability of immune cells to respond to the hormones that normally regulate inflammation, thus allowing the development and progression of some diseases.

Stress has negative effects on the entire body—the cardiovascular, respiratory, musculoskeletal, endocrine, gastrointestinal, nervous, and reproductive systems (see Fig. 43-3 on page 1771). Under normal circumstances, cortisol,

an antiinflammatory hormone released by the adrenal glands, regulates the inflammatory response, but prolonged stress may decrease the effectiveness of cortisol, or the immune cells may be resistant to its effects (American Institute of Stress, 2020; American Psychological Association, 2018; Norris, 2020). A person who reacts to stress by overeating, smoking, using alcohol or illicit drugs, or becoming hyperactive puts additional strain on the body. See the Promoting Health Literacy box for tips useful for patients experiencing long-term stress.

Promoting Health Literacy

IN PATIENTS EXPERIENCING LONG-TERM STRESS

Patient Scenario

Eva Weber is a 34-year-old single mother of twin boys. Both boys, now age 6, have had developmental delays and have been diagnosed with attention-deficit disorder. Eva has a job at a dry cleaner but worries constantly that she will not be able to keep her job since she has been late frequently because her car is old and breaks down often. Her former husband only pays child support about half the time, often because he has lost his construction job due to chronic alcoholism. When he drinks, he calls her constantly and sometimes comes to her house, beating on the door until she calls the police. She has problems sleeping and has lost 25 lb; she is 5 ft 9 inches tall and now only weighs 120 lb. She admits she drinks and smokes too much, but says, “It’s the only thing that makes me feel better for a while.” Although the nurse practitioner at the local clinic has talked to her about stopping smoking and gaining weight, Eva has not been able to do so.

Nursing Considerations: *Tips for Improving Health Literacy*

Ask Eva to keep a stress diary, noting when and how often something triggers her stress, how it makes her feel, and listing the things in her life that make her happy. Teach her how to take one day at a time, encouraging her to believe that she has control over some aspects of her life, but acknowledging that other aspects are uncontrollable. Work with Eva to do a computer search, using reputable sites, to assess her ability to access resources for her children and herself. Suggest that she ask her primary health care provider for some help in stopping smoking in the form of medications. She needs to identify appropriate support systems and create a plan to stop smoking. Explain and provide written guidelines for relaxation exercises that Eva identifies as potentially useful. Discuss methods of reducing stress other than through alcohol and nicotine, including taking time to relax, talking with a friend, and intentionally identifying positive aspects of a situation. Suggest other activities that are known to reduce stress, such as regular exercise, eating a nutritious diet, learning to say “no,” avoiding people who are stressful, being more assertive, and doing something enjoyable each day. Encourage Eva to make an appointment at the clinic and to be prepared to ask her provider the following three questions:

- What is my main problem?
- What do I need to do?
- Why is it important for me to do this?

What additional measures can you take to help maintain health literacy in this patient? What other measures would be helpful for Eva if she did not speak English, could not read, or had other learning deficits?

Unfolding Patient Stories: Vernon Russell • Part 2

Recall **Vernon Russell** from Chapter 12, a 55-year-old with a 5-year history of hypertension, coronary artery disease, and diabetes who has mild left hemiplegia from a right-sided stroke. He is divorced and living with his son, and both work at an oil refinery. What are potential sources of stress for Vernon and his son? Describe interventions the nurse can use to assist them with coping skills and stress reduction. What risks may be present for ineffective adaptation to, and coping with, his current condition?

Care for Vernon and other patients in a realistic virtual environment: vSim for Nursing (thepoint.lww.com/vSimFunds). Practice documenting these patients’ care in DocuCare (thepoint.lww.com/DocuCareEHR).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Family Stress

The stress that affects an ill person also affects the person's family members or significant others. When the family is viewed as a system, the behavior of the individual is influenced by family, and any alterations in the individual's behavior affect the family. Stressors for the family include changes in family structure and roles, anger and feelings of helplessness and guilt, loss of control over normal routines, and concern for financial stability.

Consider **Joan Rogerrio,** the woman with an exacerbation of her bowel disease. Her family is already experiencing changes related to her return to work. These changes could be possible stressors for the family. These family stressors are increased by Joan's illness, which may ultimately affect her role performance. Thus, the nurse would need to assess the family situation for the effect of these stressors on the family.

The family, both as individuals and as a unit, uses many of the same coping and defense mechanisms described previously. Family members may be overly protective, deny the seriousness of the illness, or blame health care providers for the patient's condition or behaviors. On the other hand, the family can provide the social support necessary to help the patient manage and adapt to stress. Emotional support from family members fosters open expression of feelings, and helps meet love and belonging needs. The inclusion of family members in problem solving, teaching and learning activities, and physical care helps both the patient and the family maintain their self-esteem and feelings of worth.

Caring for a family member at home for long periods can also cause prolonged stress. This stress response, called **caregiver burden**, or caregiver stress, includes chronic fatigue, sleep problems, and an increased incidence of stress-related illnesses, such as high blood pressure and heart disease. Prolonged stress can seriously threaten mental health. As coping or defense mechanisms become ineffective, a person may try less effective coping patterns or maladaptive defense mechanisms. As anxiety increases despite these measures, the person may experience difficulties on the job, with personal relationships, and with self-esteem. Although caregiving is hard work, stressful, and provokes a wide range of both positive and negative emotions, when support systems are sufficient, advocating for another person builds what is often a reciprocal, bonded relationship (Turner & Finch-Guthrie, 2020).

People who were neglected or abused as children are more vulnerable to stress as adults. An ongoing study of adverse childhood experiences (ACEs) by the CDC (2020a) and Kaiser Permanente documents and tracks the development of chronic diseases, mental health disorders, health risk behaviors, and other health and social behaviors associated with negative childhood experiences. When the abuse occurs early in a child's life and is ongoing, changes in the brain's structure and function can occur, resulting in an altered immune response to inflammation and wound healing. The family is an integral part in the assessment, planning, nursing interventions, and evaluation of actions to prevent ACEs and promote adaptation to stress.

Crisis

A **crisis** is a disturbance caused by a precipitating event, such as a perceived loss, a threat of loss, or a challenge, that is interpreted as a threat to self. In a crisis, the person's usual methods of coping are ineffective. This failure produces high levels of anxiety, disorganized behavior, and an inability to function adequately. The crisis and associated anxiety initially activate the person's usual methods of coping. If these are not effective, the person experiences more anxiety because the coping mechanisms are not working. As the crisis continues, the person tries new methods of coping or redefines the threat. This may lead to resolution of the crisis or, if not effective, may result in severe or panic levels of anxiety. The crisis is more likely to be successfully resolved if the person views the event realistically, effective coping mechanisms are present, and situational support systems are available.

Crises may be maturational, situational, or adventitious. Maturational crises occur during developmental events that require role change, such as when a teenager transitions into adulthood. Situational crises occur when a life event disrupts a person's psychological equilibrium, such as loss of a job or death of a loved family member. Adventitious crises include accidental and unexpected events resulting in multiple losses, and major environmental changes—such as fires, earthquakes, and floods—that involve not only individuals but also entire communities. Preparation for an adventitious crisis, such as active shooter drills in elementary schools, can cause stress, even with proper framing, education, and support. The stress experienced during the pandemic led to periods of fatigue and inactivity, restlessness, an inability to concentrate, loneliness, and general feelings of unhappiness in all age groups. Generation Z (ages 13 to 23

years in 2020) reported the greatest impact, with 34% of Generation Z adults reporting worse mental health than the previous year (APA, 2020). This prolonged period of crisis presented unique challenges and opportunities. This global crisis led to a collective moral fatigue and general unrest that is likely to have long-term impact on the psychological, social, and physical well-being of individuals and communities for years to come.

FACTORS AFFECTING STRESS AND ADAPTATION

Stress and adaptation are affected by the sources of stress (i.e., the types of stressors experienced) and personal factors.

Sources of Stress

Although there are an almost infinite number of sources of stress, they can be categorized into two broad areas: developmental stress and situational stress. Both require adaptive responses.

Developmental Stress

Developmental stress occurs as a person progresses through the normal stages of growth and development from birth to old age (described in Chapters 22, 23, and 24). Within each stage, certain tasks must be resolved to reduce the stress. Examples of stages of growth and development associated with developmental stress include the following:

- The infant learning to trust others
- The toddler learning to control elimination
- The school-aged child socializing with peers
- The adolescent striving for independence
- The middle-aged adult accepting physical signs of aging
- The older adult reflecting on past life experiences with satisfaction

Situational Stress

Situational stress is different from developmental stress. It does not occur in predictable patterns as a person progresses through life. Situational stress can occur at any time, although the person's ability to adapt may be strongly influenced by their developmental level. Examples of situational stress, which may be either positive or negative, include the following:

- Illness or traumatic injury
- Marriage or divorce
- Loss (of belongings, relationships, family member)
- New job
- Role change

Recall the three people described at the beginning of the chapter. All three are experiencing situational stress, but each is responding differently. **Mei Fu** is having headaches and diarrhea, **Joan** is experiencing an exacerbation of her bowel disease, and **Christopher** is feeling sick and shaky.

Consider pregnancy as an example of a situational stress. A young married couple may be overjoyed at the prospect of becoming parents, whereas an unmarried adolescent may be panic-stricken when told the pregnancy test is positive. The situations and the developmental levels of the young couple and the adolescent will have a major effect on the adaptations they will make. A person's physical and psychosocial capacities to cope with the situation depend not only on stage of maturation, but also on the support systems available.

Personal Factors

Adaptation to stress, whether positive or negative, is influenced by a number of personal factors. A person's physiologic reserve, genetics, epigenetic changes, and psychosocial factors influence a person's ability to maintain homeostasis and adapt to stressors. The ability to adapt is lower in the very young, the very old, and those with altered physical health who do not have the necessary physiologic reserves to cope with physical changes such as dehydration or fluid excess. Adequate nutrition and sleep are necessary for enzyme function, immune responses, wound healing, and energy production and restoration. Malnutrition, dietary deficits or excess, and sleep deprivation all impair a person's ability to adapt to stress. People with mental health issues may lack adaptability and flexibility because their resources, both internal and external, are already dedicated to maintaining balance; a new stressor can send them into crisis. Genetics

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

influences the number and availability of adaptive responses and the ability to choose the most effective response. For example, although the sickle cell gene is prevalent in some communities in Africa, the gene provides some resistance to malaria, which may be adaptive for those communities (Norris, 2020). Social factors and life events also affect a person's adaptation to stress. People who have strong support systems and relationships are better able to adapt to stress and remain healthy.

STRESS AND ADAPTATION IN NURSING

Nursing involves activities and interpersonal relationships that are often stressful (Fig. 43-4). Activities and situations identified as highly stressful include the following:

- Assuming responsibilities for which you are not prepared
- Working with unqualified or an insufficient number of personnel
- Working in an environment in which supervisors and administrators are not supportive
- Experiencing conflict with a peer or other member of the interprofessional team
- Caring for a patient who is suffering while also supporting the patient's family
- Caring for a patient during a cardiac arrest or for a patient who is dying
- Providing care to a patient who is disengaged, nonadherent, or lacks the resources to participate in their care
- Knowing the correct, right, or ethical course of action in a situation, but being unable to take that action (moral distress)

FIGURE 43-4. Some nursing specialties can be more stressful than others. To prevent burnout and alleviate personal stress, a nurse may need to work in another area of nursing temporarily or permanently.

This kind of stress is even greater for two specific groups of nurses: new graduates, who must adjust to an environment and role different from that experienced as students, and nurses who work in settings such as intensive care and emergency care.

Patients in hospitals are more acutely ill today than in the past. This situation, combined with a shortage of nurses, the increasing number of people older than age 65 years, technologic advances, and health care policies that impact on health care access and resources, has resulted in more stressful conditions for nurses in the workplaces. Nurses often need to work longer hours or more overtime.

In addition, nurses may have concerns about incivility, bullying, or workplace violence (American Nurses Association [ANA], 2015). Incivility encompasses rude or discourteous actions that negatively affect others. Incivility can escalate to bullying, which can be defined as repeated, ongoing actions that intend to harm another person, such as humiliation, offensive speech or actions, or other methods of causing distress. Workplace violence, which consists of actions that cause psychological or physical damage, can be perpetrated by: (1) someone who has no relationship with the victim (crime-based); (2) a customer, client, or patient; (3) a co-worker, who may or may not be a peer; or (4) someone involved in a personal relationship with the victim (ANA, 2015). Nurses may worry not only about the future of their positions, but also about the safety of their patients, and may harbor concerns about their own personal safety. The anxiety is complicated by the expectations of nurses to provide compassionate, person-centered care in sometimes challenging situations. Creating a culture of respect within the profession and our workplaces promotes positive interpersonal and interprofessional relationships, and improves the physical and psychological well-being of nurses (ANA, 2015).

Student nurses also experience stress related to the difficulty of adapting to the requirements and responsibilities of caring for others. Other factors causing stress in student nurses include the following:

- Fear of failing the classroom or clinical laboratory components of each course
- Fear of failing the licensure examination after graduation
- The physical, emotional, cognitive, and psychological demands of the nursing program
- Fear of injuring patients

- The need to balance work, home, and school
- The need to meet financial and family responsibilities

Recall **Christopher Weiss,** the nursing student described in the Reflective Practice display. He was feeling overwhelmed with the responsibilities of caring for patients in a high-tech environment. This feeling was compounded by his concerns about the assigned instructor. Subsequently, Christopher began to feel ill.

Most nurses and student nurses enjoy their education and work, coping with physical and emotional demands effectively. Some, however, become overwhelmed and develop symptoms of stress, or a complex set of behaviors and emotions called **burnout**. Burnout can be compared with the exhaustion stage of anxiety and is characterized by a wide range of behaviors. Some nurses try to become "supernurses," expecting perfection in themselves and others. Some withdraw and do only minimal work, while still others resort to drugs or alcohol. Nurses must acknowledge their stress and secure the necessary personal and professional resources to adapt and cope or they may end up leaving the profession. Refer to the Research in Nursing box (on page 1778) for a discussion of resilience practices.

What can graduate and student nurses do to help reduce stress and prevent burnout? The first step in preventing a stress level high enough to cause burnout is to identify and accept the stress. The same stress-reduction techniques that are used for patients have positive benefits for nurses. Nurses must accept that they have the same needs and are as individual as their patients. Largely in response to the pandemic, the American Nurses Foundation of the ANA, in partnership with the Emergency Nurses Association (ENA, https://www.ena.org/), the American Association of Critical-Care Nurses (AACN, https://www.aacn.org/), the American Psychiatric Nurses Association (APNA, https://www.apna.org/i4a/pages/index.cfm?pageid=1), and the Association of periOperative Registered Nurses (AORN) launched the *Well-Being Initiative*. The site links to free tools and apps designed to support the mental health and well-being of nurses. Specific topics include cultivating gratitude, narrative expressive writing, sleep assistance, access to therapy, suicide prevention, and other topics designed to support nurses and foster resilience (ANA Enterprise, 2021). By recognizing the early signs of stress and taking steps to reduce it, nurses can continue to be effective, productive, and satisfied in the profession (see Focused Critical Thinking Guide 43-1 on page 1782).

Research in Nursing

Bridging the Gap to Evidence-Based Practice

Resilience in Nursing

There has been an emphasis on building individual, collective, and organizational resilience in nursing. Resilience generally refers to the ability to withstand or adapt to adversity, stress, or trauma. It requires a responsive flexibility and includes neurobiologic, psychological, and social ecologic components (Rushton, 2018). Although wellness initiatives, an emphasis on self-care, and the integration of concrete mindful and reflective practices support nurses in developing their individual resilience, individual resilience is not enough to mitigate the complexities in health care systems that often lead to moral distress (Rushton, 2018; Wocial, 2020). A systems approach holds health care organizations, professional organizations, governing and regulatory bodies, and the public accountable for the health and well-being of health care professionals. This approach supports the development of viable processes to mitigate moral distress, decrease microaggressions, and eliminate burnout. Nurse leaders are crucial for the successful implementation of initiatives focused on changes at the systems level that foster nurse resilience and, ultimately, lead to improved patient outcomes.

Related Research

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Wei, H., Roberts, P., Strickler, J., & Corbett, R. W. (2019). Nurse leaders' strategies to foster nurse resilience. *Journal of Nursing Management*, *27*(4), 681–687. https://doi.org/10.1111/jonm.12736

This qualitative descriptive study from November 2017–June 2018 involved 20 nurse leaders and explored their perspectives on effective strategies to foster nurse resilience. The nurse leaders were charge nurses (n = 8), nurse managers (n = 8), and nurse executives (n = 4) from a tertiary hospital in the United States. The participants were predominantly female (n = 18), Caucasian (n = 16), and younger than age 56 years (n = 17). Through qualitative interviews and the associated phenomenologic-based analytical framework, seven resilience-cultivating strategies were identified: (1) facilitating social connections and acts of kindness, (2) promoting positivity through role modeling and practicing gratitude, (3) capitalizing on nurses' strengths and creativity, (4) nurturing nurses' growth personally and professionally, (5) encouraging nurses' self-care and establishing a supportive work environment, (6) fostering mindfulness practice, and (7) conveying altruism through the creation of caring connections and meaningful recognition.

Relevance to Nursing Practice

Nurse leaders make a difference in building resilience in their teams. The specific initiatives described in the interviews were generally simple, focused on the nurses, and were collaborative in nature. A systems approach to building resilience in the workplace can begin with nurse leaders.

NURSING PROCESS FOR THE PATIENT WITH STRESS AND ANXIETY

Self-awareness of stress and anxiety is essential when caring for patients. Nurses who role-model good health behaviors are more effective teachers. Use the tool found in Promoting Health 43-1 for yourself before using it with others.

Remember **Joan Rogerrio,** the woman returning to work after an absence of 15 years. The nurse could use the tool in Promoting Health 43-1 (on page 1780) as part of the patient's assessment. Then the nurse could use those items identified as *sometimes* and *almost never* as a basis for teaching Joan measures to adapt and cope with her stressors.

Assessing

Stress and anxiety are problems that nurses encounter in patients of all ages and in all settings. Stress is assessed through a health assessment, which includes a nursing history and physical assessment. Risk factors for, or indicators of, stress may be identified through standardized tests or open-ended questions to elicit information. The patient's willingness to share information is affected by the level of stress experienced as well as the coping or defense mechanisms in use.

Nursing History

The nursing history assists the nurse in identifying stressors and how the person perceives and copes with stress. Manifestations of anxiety, as well as questions and leading statements to identify stress and anxiety, are listed in the Focused Assessment Guide 43-1 on page 1780.

Physical Assessment

There are no specific guidelines for the physical assessment of stress. Physical indicators of stress, in addition to those listed in the Focused Assessment Guide, may include cardiac dysrhythmias, chest pain, headache, hyperventilation, diarrhea, tense muscles, and skin lesions, such as eczema. These manifestations are the result of the mind–body interaction described earlier.

Diagnosing

Assessment data may reveal stress to be the actual or potential problem, or stress may be the etiology of another

problem. See the accompanying display, Examples of Actual or Potential Health Problems and Needs: The Patient Experiencing Stress on page 1780.

Promoting Health 43-1

STRESS AND ADAPTATION

Nurses who design care plans for patients to reduce stress must also consider themselves a factor in the success of that care plan. The nurse who wishes to encourage healthy adaptation to stress must demonstrate behaviors that support a healthy lifestyle. Use the assessment checklist to determine how well *you* are adapting to stress. Then develop a prescription for self-care by choosing the appropriate behaviors from the list of suggestions.

Assessment Checklist

☐ almost always ☐ sometimes ☐ almost never

☐	☐	☐	1. I have realistic perceptions of new situations, self, and others.
☐	☐	☐	2. I understand my own personal physical and emotional responses to stress.
☐	☐	☐	3. I anticipate and prepare for change.
☐	☐	☐	4. I have the ability to satisfactorily solve problems and make decisions.

Self-Care Behaviors

1. Accept the changes that come with different parts and stages of life as positive indicators of growth.
2. Maintain an open mind about change—change what you can and accept what you cannot change.
3. Avoid self-defeating behaviors to cope with stress such as smoking, alcohol, and drugs.
4. Avoid confrontational and unprofessional interactions with other staff members—engage in civil discourse.
5. Develop a greater awareness of potential risks in the workplace that can result in violence.
6. Practice methods of stress management that work best for you: relaxation techniques, exercise, hobbies.
7. Set realistic goals.
8. Develop problem-solving strategies for use in stressful situations.
9. Accept help from others.
10. Take life one day at a time—embrace the concepts of mindfulness and centering.

Stress as the Problem

The following problems may be identified when stress is the problem (International Council of Nurses [ICN], 2019):

- Stress overload related to single parenthood, inadequate economic resources, and chronic illness
- Moral distress related to cultural conflicts, end-of-life decisions, conflicting information about ethical decision making, or treatment decisions

Stress as the Etiology

Stress and anxiety may affect many other areas of human functioning. In the following problems, stress and anxiety are involved in the etiologies of other problems (ICN, 2019):

- "Caregiver stress related to the long-term stress of caring for a parent with dementia, as evidenced by the statement," "I am just at my wits ends trying to keep mom safe!"
- "Impaired spiritual status related to the stress of a new terminal diagnosis, as evidenced by the statement," "God has forsaken me"
- Hopelessness related to presence of disabling physical injuries, as evidenced by statement, "I give up … it's just not worth it," apathy, visible lack of engagement

Outcome Identification and Planning

The nurse plans and implements care to decrease anxiety and facilitate adaptation in the patient with stress. The expected outcomes of the plan must be mutually determined with the patient or family members. Examples of expected outcomes are as follows:

The patient will:

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Decrease the level of anxiety by verbalizing feelings and using support systems.
- Develop effective methods of coping through problem-solving skills and anxiety-reducing techniques.
- Describe a reduction in anxiety and an increase in comfort.
- Identify three concrete stress-reduction techniques that are of interest.
- Identify resources to manage moral distress (see Chapter 6) and spiritual distress.

Implementing

Nurses may use a variety of interventions to help patients decrease stress and to facilitate coping. Methods should be selected carefully based on the person's physical and emotional characteristics, family and social structure, and previously used successful coping mechanisms. Guidelines for Nursing Care 43-1 on page 1781 list nursing interventions to reduce stress and anxiety for patients as they enter a health care setting.

If the patient's anxiety seems too great or if the nurse is uncomfortable with the interventions, a referral should be made to a professional counselor. The patient may also be helped by meeting with a spiritual advisor (rabbi, minister, priest, etc.) or people who have experienced the same type of surgery or health problem. (see Focused Critical Thinking Guide 43-1 on page 1782).

Focused Assessment Guide 43-1

ANXIETY PRECIPITATED BY STRESS

Factors to Assess	Questions and Approaches
Subjective data	• "Have you noticed that you sometimes feel your heart beating or have difficulty breathing?"
Heart palpitations	
Difficulty breathing	• "Tell me about your appetite and sleep."
Problems with appetite or sleep	• "Of the following, which best describes how you are feeling: sad, apprehensive, angry, mistrustful, helpless, hopeless?"
Feelings of sadness, apprehension, anger, mistrust, helplessness, hopelessness	• "Tell me about any changes you have noticed in your sexual desire."
Changes in sexual desire	• "How does your body feel when you are upset?"
Objective data	• Note body posture and movements.
Dry mouth	• Inspect skin and mucous membranes.
Increased perspiration	• Take and record vital signs.
Tremors	• Note general affect.
Tachycardia	
Increased blood pressure	
Dilated pupils	
Crying	
Restlessness	
Rapid speech	
Pacing around the room	
Lack of facial expression	
	• "You have been very quiet today. Has something happened since our last visit?"
Ability to verbalize anxiety	• "It must be very frightening to be told that you have cancer."
	• "I notice you seem upset. Would you like to talk about it?"
	• "What has caused you to feel stressed in the past?"
	• "What do you do to feel better when you feel anxious?"

Examples of Actual or Potential Health Problems and Needs

THE PATIENT EXPERIENCING STRESS

Actual or Potential Health Problem or Need	Possible Etiologic Factors	Potential Signs and Symptoms
Anxiety	• Conflicts about values and goals in life • Threat to self-concept, threat of death, threat of change in health status, threat to environment or role • Situational/maturational crisis • Unmet needs	• Verbalizations of anxiety • Impaired decision making • Nervous behaviors: pacing, twitching, picking, frequent movements, or shaking • Impatience or anger • Physiologic changes such as tachycardia or tachypnea
		—
Coping Impairment	• Previous coping mechanisms ineffective or insufficient	• Signs of anxiety or depression • Verbalization of coping issues

- Inability to identify coping strategies
- Inability to identify or employ internal or external resources
- Lack of experience with stress
- Decreased adaptability

- Negative physical, psychological, emotional, or behavioral changes

Source: International Council of Nurses (ICN). (2019). *Nursing diagnosis and outcome statements*. https://www.icn.ch/sites/default/files/inline-files/ICNP2019-DC.pdf; Wolters Kluwer. (2022). Problem-based care plans. In Lippincott Advisor. Wolters Kluwer. https://advisor.lww.com/lna/home.do

Guidelines for Nursing Care 43-1

Reducing Anxiety on Admission to a Health Care Facility

1. Assess physical status, sensory status, and cognitive status.
2. Assess cultural/ethnic background, including beliefs about health care, dietary restrictions, and language spoken.
3. Assess past experiences with the health care system, including medical-surgical treatment for illness or injury.
4. Assess concerns and stressors.
5. Assess number and type of support systems available.
6. Provide information about the environment:
   a. Ensure that all health care providers introduce themselves by name and title.
   b. Explain policies and routines.
   c. If the hospital is the setting, provide verbal and written guidelines for use of equipment, telephone, and television. Also provide information about meals and visiting hours.
7. Provide and discuss the patient's rights specific to care in the facility.
8. Mutually determine expected outcomes of the plan of care.
9. Provide information about all diagnostic procedures, surgical procedures, activity, and diet.

Teaching Healthy Activities of Daily Living

A person's usual lifestyle greatly influences that person's perceptions of and reactions to stressors. Exercise, rest, and good nutrition are important components of stress reduction, so it follows that a person who is overweight, sedentary, and chronically sleep-deprived is at increased risk for developing an illness as a result of stress.

Think about **Christopher Weiss's** lifestyle as a student nurse. His school-related workload places Christopher at risk for stress. In addition, other factors, such as demands from family members or a need to work part-time, decrease his ability to maintain a healthy lifestyle that includes regular exercise, rest, and good nutrition.

EXERCISE

Regular exercise helps maintain physical and emotional health. The benefits of exercise include an improved musculoskeletal system, more effective cardiovascular function, weight control, and relaxation. Exercise improves a person's general sense of well-being, relieves tension, and enables coping with day-to-day stressors. General health guidelines recommend that an exercise program consists of 30 to 45 minutes of moderate activity above usual activity on most days of the week. People who are overweight, chronically ill, or older than age 35 years should have a physical examination before beginning such a program. The type of exercise depends on what the person enjoys—for example, walking, jogging, bicycling, swimming, or sports such as golf or tennis.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

REST AND SLEEP

Rest and sleep help the body maintain homeostasis and restore energy levels. Adequate rest can provide insulation against stress, but stress may interfere with a person's ability to sleep. Each person has individual sleep needs, but 7 to 9 hours of sleep a day is the usual recommendation. Relaxation techniques can be used during both health and illness to facilitate rest and sleep. Hospitalized patients may require additional nursing interventions to relieve pain and promote comfort to get needed rest.

NUTRITION

Overeating food that is not nutrient-dense, severely limiting intake, and craving a specific food are common (often negative) coping strategies that need to be considered when addressing stress and coping mechanisms. Nutrition plays an active role in maintaining the body's homeostatic mechanisms and in increasing resistance to stress. (Nutrition is discussed in detail in Chapter 37.) Obesity and malnutrition are major stressors and greatly increase the risk for illness. New 2020–2025 Dietary Guidelines for Americans includes a call to action, "Make Every Bite Count with the Dietary Guidelines" (U.S. Department of Agriculture & U.S. Department of Health and Human Services, 2020). This initiative focuses on choosing nutrient-dense foods and portion control to stay within the stage-of-life-specific calorie recommendations. This means limiting sugars, saturated fat, and alcohol intake to about 15% of calories. In the United States, there is public health concern over the dietary intake of calcium, potassium, fiber, vitamin D, and iron, so standard portions and smaller portions of nutrient-dense foods are specifically addressed in the recommendations. To allow for cultural, budgetary, and lifestyle choices, the guidelines are adaptable and not prescriptive, but they do encourage assessing and developing a pattern of healthy eating and not focusing on a specific food or meal (U.S. Department of Agriculture & U.S. Department of Health and Human Services, 2020). Check out the specific guidelines and teaching materials for you and the populations you serve at https://www.dietaryguidelines.gov/resources/2020-2025-dietary-guidelines-online-materials

43-1 Focused Critical Thinking Guide

Stress and Anxiety

You are a senior nursing student in a community health course. You have been assigned to visit and provide ongoing assessments for Charles Obedide, a 28-year-old man who was involved in a serious motorcycle crash a year ago and is paralyzed from the waist down. Charles initially participated fully in his rehabilitation, and has been living independently in an apartment that is wheelchair accessible. However, a month ago, Charles was ill for 2 weeks, lost his job, and broke up with his girlfriend. When you made your last home visit, Charles was restless, had an increased pulse, and did little talking. At today's visit, Charles is wearing dirty clothes and has a strong body odor. There are several empty beer cans on the table in the kitchen. Charles begins to cry, saying, "I am so upset—I can't sleep or eat—I need help." What would you do?

1. Identify goal of thinking

Identify the level of anxiety experienced by Charles and begin interventions to help Charles decrease his level of anxiety.

2. Assess adequacy of knowledge

Pertinent circumstances: Charles has had numerous losses in the past year, including loss of body function and changes in body image. He has recently lost his job, a major source of economic support and self-concept. He separated from his girlfriend, a major source of support. Previously, Charles was clean and well groomed. There was no previous evidence of drinking. His parents live nearby and are supportive and loving. These stressors are manifesting as anxiety in Charles.

Prerequisite knowledge: Before you decide what to do in this situation, you need to assess the level of stress and associated anxiety experienced by Charles. You need to know the typical behaviors of each level and be able to recognize that Charles has severe anxiety. You must recognize that Charles needs interventions to regain equilibrium.

Room for error: Charles requires and has asked for help. You are unsure of your abilities to help him deal effectively with his anxiety. You realize that his frustration with the situation could make him angry. You also know that depression and the potential for self-violence are risks unless something is done to reduce his anxiety.

Time constraints: Although you are not certain about how serious his problem is, you understand that Charles needs help in reducing his anxiety soon. There is time for you to ask for guidance from your instructor.

3. Address potential problems

There are several potential barriers to critical thinking in this situation. You realize Charles needs help in

reducing his level of stress, which in turn causes you anxiety. You are also somewhat frightened about his appearance and behavior. You do not believe your own abilities are developed well enough to help Charles adequately, but at the same time, you do know he needs help. You are comfortable sitting with Charles, making eye contact, and being present with him. Although he is not very talkative, making sure he is not alone and receives compassionate care in this moment is important.

4. Consult helpful resources

Your best source of information is Charles himself. You ask him what you can do to help him. He replies, "Just get someone here to help me." You ask his permission to call his mother and he agrees. His mother says she will be there in 5 minutes. You call your instructor, and she tells you to call the home health care facility for further instructions.

5. Critique judgment/decision

When his mother arrives, she says she had no idea he was so distressed. She talks to the home health care facility staff, who report that they have called Charles's health care provider and will continue to follow up on needed care and referrals for professional counseling. You believe you made the right decisions: you identified that Charles needed help, you provided compassionate support in the moment, you contacted his mother to provide support, you contacted your instructor, and you contacted the home health care facility. You also remained calm during the situation, despite your own anxiety.

Encouraging Use of Support Systems

Families and support groups provide emotional support that can help a person identify and verbalize feelings associated with stress. In addition, families and support groups provide an accepting environment, allowing the person to explore problem-solving methods and try out new coping skills. Support groups, aside from providing information and services, may help a person maintain a positive self-concept and establish an avenue for new relationships and social roles. There are support groups for almost every situation; examples are listed in Box 43-5 on page 1783.

Encouraging Use of Stress Management Techniques

Stress creates emotional distress that often produces physical signs and symptoms. One person may have tension headaches, another may become irritable, and yet another may clench both fists. Some people take legal or illegal drugs, smoke, drink to excess, or eat compulsively. These behaviors can be modified, and adaptive mechanisms can be strengthened through specific techniques aimed at managing stress. Only a few techniques are included here, but the literature describes many stress reduction methods, including exercise, prayer, art therapy, music therapy, massage, and therapeutic touch. Chapter 29 provides more information. Students should learn different methods they can use for themselves and in varied clinical situations.

RELAXATION

Relaxation techniques are useful in many situations, such as childbirth, pain, anxiety, sleeplessness, illness, and anger. Relaxation promotes a body reaction opposite to that of the fight-or-flight response: respiratory, pulse, and metabolic rates, as well as blood pressure and energy use, can all be decreased using relaxation methods.

Box 43-5 **Examples of Support Groups**

Alcoholics anonymous
Assertiveness training groups
Child abuse support groups
Ostomy clubs
Overeaters anonymous
Parents without partners
Reach to recovery (cancer)
Stroke clubs
Sudden infant death support groups
Weight Watchers

Look also for online support groups sponsored by professional organizations or individuals with similar issues. See Healthfinder.gov, a website of the Office of Disease Prevention and Health Promotion, U.S. Department of Health and Human Services, to locate a support group.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Relaxation can be taught to individuals or groups. It is especially helpful because it allows people to control their feelings and behaviors. Relaxation techniques include progressive relaxation (tensing, then relaxing), autogenic training (focused mental exercises), guided imagery, biofeedback-assisted relaxation, self-hypnosis (uses suggestions), and breathing exercises (diaphragmatic breathing; National Center for Complementary and Integrative Health [NCCIH], 2021). Relaxation is discussed as a comfort measure in Chapter 36. See Guidelines for Nursing Care 43-2 for a description of deep breathing and progressive muscle relaxation.

MINDFULNESS

Mindfulness practice has been widely implemented in health care in the past few years. Mindfulness requires intentional presence and focus on the moment. Curiosity, openness, and acceptance without judgment support the centering. Meditation and breathing exercises may be used to support the mindfulness practice. Forest bathing or *shinrin-yoku*, the Japanese-based practice of opening the five senses to connect with the natural world in the present moment, provides another method of engaging in mindfulness. Psychological and physical benefits include stress and anxiety reduction; improvement in cardiovascular and immune health; and increases in energy, concentration, and creativity (Li, 2018). Mindfulness practices may positively impact nurses by decreasing their stress, anxiety, depression, and burnout while increasing their well-being and capacity for empathy (Chmielewski et al., 2021).

Guidelines for Nursing Care 43-2

Relaxation Activities

Deep Breathing

1. Sit comfortably and place your hands on your stomach. Inhale slowly and deeply, letting your abdomen expand as much as possible. Hold your breath for a few seconds.
2. Exhale slowly through your mouth, blowing through puckered lips. When your abdomen feels empty, begin again with a deep inhalation.

Progressive Muscle Relaxation

1. Tighten your hand into a fist and notice how it feels. Hold the tension for a few seconds.
2. Loosen your grip, relax the muscles in your hand, and let the tension slip away.
3. Continue to tighten–hold–relax each muscle group, moving head to toe: face, shoulders, arms, chest, back, abdomen, legs, and feet.

Christopher Weiss, the student nurse, could learn to perform relaxation exercises or practice meditation. Both techniques would be helpful in reducing his stress.

ANTICIPATORY GUIDANCE

Anticipatory guidance focuses on psychologically preparing a person for an unfamiliar or painful event. Nurses use this technique when they teach patients about procedures and the surgical experience. When patients know what to expect, their anxiety is reduced and their coping mechanisms are more effective. For example, before performing a painful procedure (such as ambulating for the first time after surgery), teaching would include information about the pain involved, including onset, severity, cause, and methods of relief. With this knowledge, the patient feels less threatened and tolerates the procedure more easily.

A related process is anticipatory socialization, in which people prepare themselves for roles to which they aspire but do not yet occupy. Parenting classes taken before the birth of a child or an internship/externship provide good examples of this activity.

GUIDED IMAGERY

In guided imagery, a person creates a mental image, concentrates on the image, and becomes less responsive to other stimuli (including pain). The nurse sits by the patient and reads a description of a scene or an experience that the patient has described as happy, pleasant, or peaceful. The patient is then "guided" through the image. For example, using a soothing, soft voice, the nurse might start as follows: "You are floating in your swimming pool. The water is cool and comfortable. Birds are singing in the trees. The roses are perfuming the air." As the patient becomes more and more focused on the scene, the nurse needs only to verbally "paint the picture" at intervals.

Providing Crisis Intervention

A crisis is a situation that cannot be resolved by usual coping mechanisms. As a result, the person cannot function normally and requires interventions to regain equilibrium. **Crisis intervention** is a short-term management technique focused on reducing damage to an individual or group affected by a crisis, often a mental or medical health emergency. The crisis may require community resources, such as a local mobile crisis team, to diffuse. The need for crisis intervention may arise with individuals or groups of any age and may be triggered by internal psychological processes or external factors, such as natural or manmade disasters (Wang & Gupta, 2021). Although there are several models of crisis intervention and the contextual elements of the crisis need to be considered, the SAFER-R model is often used as a beginning framework for individual crisis intervention (Everly & Mitchell, 2017):

1. *Stabilization.* Introduce yourself and establish your role and that of the other people involved. Meet basic needs, consider safety of all parties, and mitigate any acute stressors if possible.
2. *Acknowledgment.* Acknowledge the precipitating event and the reactions of the individual.
3. *Facilitation of understanding*. Paraphrase and reflect back to the individual what they are experiencing. Normalize their reaction to a stressful event and work to minimize feelings of personal weakness.
4. *Encourage effective coping*. Tap into their existing coping tools and resources and identify external sources of support to facilitate coping.
5. *Recovery*. Assess and establish the person's ability to function safety.
6. *Referral.* Make referrals as needed.

The major factor in helping patients adapt to high levels of stress is to identify and plan individually for situations causing the stress. Maintaining immediate safety is a priority. Facilitate the patient's recognition of their own stress level and specific responses to stress. Encourage adoption of a philosophy of accepting what cannot be changed and changing what cannot be accepted. Emphasize the importance of accepting help from others and giving support to others when needed as well as being actively involved in problem solving and decision making. Nurses must use therapeutic communication skills in all interactions but must be especially cognizant of their words and actions in a crisis situation.

QSEN SAFETY

Promoting safety is an overriding priority in crisis management. Consider whether the individual (or group) is in danger of self-harm or harm from others. Also consider environmental safety and whether the person (or group) in crisis is a danger to others. Once any immediate safety concerns are addressed, engage in crisis-management techniques that are appropriate for the situation.

Crisis Standards of Care

Crisis standards of care may be considered during times of mass crisis when resources (equipment, space, or trained personnel) are insufficient to meet the demands. It involves careful consideration of the circumstances and available resources, and equitable allocation of available resources. In a crisis, the health care system may not be able to maintain usual approaches to care. We may be forced to implement contingency care that requires reworking strategies, including staffing decisions, space designation, and resource conservation to maintain the delivery of functionally equivalent care. If the system is taxed further, crisis standards of care may be implemented, which requires a systems approach (The Commonwealth of Massachusetts, Executive Office of Health and Human Services Department of Public Health, 2020). It is important to remember that these processes stress the individuals involved, but the stress experienced by the entire system can be mitigated by planning and regularly reevaluating processes and decisions.

Evaluating

The evaluation of the plan of care is based on the mutually established expected outcomes. Be sure to observe both verbal and nonverbal cues when evaluating the usefulness of the plan. In general, the plan is considered successful if the patient and those important to them have been able to do the following:

- Verbalize causes and effects of stress and anxiety

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Identify and use sources of support
- Use problem solving to find solutions to stressors
- Practice healthy lifestyle habits and anxiety-reducing techniques
- Verbalize a decrease in anxiety and an increase in comfort

REFLECTIVE PRACTICE LEADING TO PERSONAL LEARNING

Remember that the object of reflective practice is to look at an experience, understand it, and learn from it. As you begin to develop your expertise in identifying and responding to stress and adaptation needs, reflect on your experiences—successes and failures—in order to improve your practice. How can you do it better next time? What did you learn today that can help you tomorrow? Begin your reflection by paying close attention to the following:

- How aware are you of developmental and situational stressors and stress? Are you able to articulate key manifestations of stress?
- What value do you attach to involving the patient in stress management techniques? How do you individualize the care for patients?
- How do you plan to hone your skills in managing the complexities of stress that can involve psychological and physiologic aspects?

Keeping up with the latest evidence-based practice guidelines can be challenging. New technology and techniques in stress management continue to be developed to combat perceived stressors. Developing a working knowledge of the core principles of stress and stress management provides a foundation for your nursing practice.

Perhaps the most important questions to reflect on are: Are your patients and families/caregivers better for having had *you* share in the critical responsibility of partnering with them to ensure appropriate skin and wound care? Are your patients now receiving thoughtful, person-centered, prioritized, holistic, evidence-based treatment and care because of your efforts?

Nursing Care Plan for Mei Fu 43-1

Remember Mei Fu, the 24-year-old graduate student with a husband and two small children. At her clinic appointment, the nurse conducted a health history and physical assessment of Mei Fu and noted the following data:

- Patient is a thin woman who appears her stated age. She is currently in school and expects herself to make the highest grades. She also cares for her two children and her husband. Although her husband encourages her to go to school, he believes it is the wife's responsibility to provide all child and house care. She has had no previous serious illnesses or surgery.
- Patient reports having frequent headaches, rating the pain as a 3 on a scale of 0 (no pain) to 10 (worst possible pain). She also reports having four to six bowel movements each day, sometimes with abdominal cramping. The diarrhea does not seem to be related to any type of foods eaten. Both the headaches and the diarrhea have been present for the past 2 months. During the interview, the patient appeared restless and talked rapidly. Questions often had to be repeated.
- Physical assessment reveals slight tachycardia, a fine hand tremor, and visible perspiration. Large muscle groups are tense and fists clenched. No tenderness is noted on abdominal palpation. Pupils are equal in size and react to light and accommodation. Nasal mucosa is normal.

ACTUAL OR POTENTIAL HEALTH PROBLEMS OR NEED

Anxiety

Etiology: stress of achievement in school and care of family

Signs and Symptoms: rapid speech, tachycardia, tremor, tense muscles, headache, and diarrhea

Goal: Patient reports experiencing a decrease in anxiety.

EXPECTED OUTCOME

By her return appointment in 2 weeks, 10/20/25, Mei Fu will:

- Identify sources of and responses to stress

NURSING INTERVENTIONS	RATIONALE	EVALUATIVE STATEMENT
Ask Mei Fu to keep a diary of hours spent in school-related activities and	Identifying sources of stress and the physical responses to stress is the	10/20/25 Outcome met. Mei Fu kept a diary as requested. She identified that

family care, number and times of headaches, and circumstances that occurred before diarrhea.	first step in planning coping strategies to reduce stress.	she does not have any time for herself. Her headaches are worse during the week. She often has diarrhea when papers are due or when her husband and children are demanding of her time. *S. Aird, RN, FNP*

EXPECTED OUTCOME

By her return appointment, 10/20/25, Mei Fu will:

- Identify sources of personal strength and support

NURSING INTERVENTIONS	RATIONALE	EVALUATIVE STATEMENT
Ask Mei Fu to make a list of the people who are important to her and provide her comfort and discuss how these people can help her cope with her situation.	Identifying support people provides the patient with the means to manage stress and enhances self-concept.	10/20/25 Outcome met. Mei Fu stated that her family is her greatest source of support, but they are in China and she misses them very much. She does have a very good friend who is also a good listener. She identified her strengths as being a person who cares for others and a good student. She said she is also a good artist but has not had time for art for months. *S. Aird, RN, FNP*
Ask Mei Fu to create a list of her strengths as a woman, a mother, a wife, and a student.	Recognizing strengths provides an opportunity to build confidence and mobilize internal coping mechanisms	

EXPECTED OUTCOME

By her return appointment, 10/20/25, Mei Fu will:

- Describe lifestyle changes that include eating a well-balanced diet with three meals a day, walking for 20 to 30 minutes four times a week, and sleeping restfully 7 hours a night

NURSING INTERVENTIONS	RATIONALE	EVALUATIVE STATEMENT
Provide Mei Fu the Dietary Guidelines for Americans and review the importance of healthy eating patterns that include eating three meals a day and include any specific cultural preferences.	Adequate nutrition helps maintain the homeostatic mechanisms of the body and increases resistance to stress.	10/20/25 Outcome met. Mei Fu was given a copy of the Dietary Guidelines for Americans and food preparations were discussed. Although the Fu family has a healthy diet, Mei Fu often was too busy to eat more than a few bites. She said that she is making a big effort to eat three times a day. She is walking to school and enjoys the time by herself. She arranged this time by asking her husband to take the children to school. She is sleeping better, and averages 7 hours most nights. *S. Aird, RN, FNP*
Teach Mei Fu about the physiologic and psychological effects of regular exercise in reducing stress.	Exercise improves well-being, relieves tension, and facilitates coping with daily stressors.	
Discuss with Mei Fu the importance of sleep in reducing stress.	Adequate rest and sleep restore energy and facilitate coping with stressors.	

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

EXPECTED OUTCOME

By her return appointment, 10/20/25, Mei Fu will:

- Practice relaxation for 20 minutes each day

NURSING INTERVENTIONS	RATIONALE	EVALUATIVE STATEMENT
Teach and have Mei Fu practice progressive muscle relaxation.	Relaxation promotes a response opposite to the stress response; it decreases heart rate, respiratory rate, blood pressure, and metabolic processes.	10/20/25 Outcome met. Mei Fu said that at first she had difficulty in finding time to be alone, but she feels so much better after she relaxes that she insists on the time. She found an online site she "really likes" and says it helps her "very much." *S. Aird, RN, FNP*
Teach Mei Fu how to access and use free online resources for relaxation techniques.	Free resources that are easily accessible are more likely to be used by this busy college student.	
Create a calendar with Mei Fu outlining time for intentional, mindful relaxation exercises.	Time constraints are the primary concern for this patient. Writing things into a calendar promotes accountability and provides a means to communicate with her family when she needs to block time for relaxation.	

EXPECTED OUTCOME

By her return appointment, 10/20/25, Mei Fu will:

- Report a decrease in signs and symptoms of stress, headaches, and diarrhea

NURSING INTERVENTIONS	RATIONALE	EVALUATIVE STATEMENT
Assess frequency and severity of headaches and bowel movements.	Decreasing stress in daily life often is effective in decreasing physical responses. Self-care of stress is critical in effective management.	10/20/25 Outcome met. Mei Fu reports she has noticed fewer headaches in the past week, and the diarrhea is almost gone. Mei Fu verbalized the importance of continuing to practice a healthy lifestyle and relaxation. She said she has spent time with her friend and has gotten out her sketch pad. She stated that she believes she can manage her life much better now. *S. Aird, RN, FNP*
Create a log to track use of coping mechanisms and their effect on managing stress.	Tracking the short- and long-term effectiveness of stress management techniques provides the patient the opportunity to reflect on time spent and efficacy of individual measures taken.	

SAMPLE

10/06/25, 1000, nursing

DOCUMENTATION

Initial visit to student health center by Mei Fu to discuss physical problems of headache and diarrhea. History and

physical assessment findings indicated large number of personal stressors, manifested by physical signs and symptoms. Assessment data supported problem identification: Anxiety related to stress of achievement in school and care of family. Discussion centered on identifying sources of stress, physical responses to stress, sources of support, and personal strength. Teaching strategies included diet, exercise, sleep, and progressive muscle relaxation. Patient to keep a log/diary of stressors and coping mechanisms. Patient's progress will be monitored at next visit on 10/20/25.

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

. Review the Nursing Care Plan 43-1 on pages 1785–1787 to help you hone your clinical reasoning and clinical judgment skills.
. Identify the nursing activities and relationships that cause you the most stress. What are your personal warning signs that a situation is becoming stressful? What do you do to decrease your level of stress? Who is most important in helping you do this?
. List nursing interventions you would use to reduce stress in the following situations:

- A newly married young woman who found a lump in her breast and is undergoing a breast biopsy.
- The parents of a 2-year-old who are sitting in the surgical waiting room as their child undergoes brain surgery.
- The daughter (and caregiver) of a woman with severe Alzheimer disease.

PRACTICING FOR NCLEX

. A nurse is assessing a patient who reports their migraines have become "unbearable." The patient states, "I got laid off from my job last week, and I have two kids in college. I don't know how I'm going to pay for it all." Which effects of physiologic effects of stress would the nurse expect to find in this patient? Select all that apply.

a. Increased or decreased appetite
b. Changes in elimination patterns
c. Decreased pulse and respirations
d. Use of ineffective coping mechanisms
e. Withdrawal
f. Attention-seeking behaviors

. A nurse who performs preoperative assessments and teaching prepares patients for postoperative discomfort using anticipatory guidance. What interventions would this nurse use to decrease postoperative stress?

a. Teaching rhythmic breathing to perform prior to the procedure
b. Telling the patient to mentally place themselves in a pleasant place and breathe in and out slowly
c. Explaining about expected incisional discomfort or nausea and describing relief methods
d. Suggesting the patient create and focus on a mental image during the procedure to be less responsive to the pain

. A nurse in a medical practice has assessed a patient reporting abdominal pain, diarrhea, and anxiety. When the health care provider finds no identifiable cause for the symptoms, which actions would the nurse recommend? Select all that apply.

a. Keeping a diary identifying sources of stress
b. Sleeping 4 hours per night
c. Considering previous strengths and coping
d. Asking whom the patient relies on for support
e. Asking if the patient's partner is abusive
f. Assessing for prior psychiatric conditions

. A nurse is assessing the developmental levels of patients in a pediatric office. Which person would a nurse document as experiencing developmental stress?

a. Infant who learns to turn over
b. School-aged child learning to add and subtract
c. Adolescent who is a "loner"
d. Young adult who has a variety of friends

. A nurse in a long-term care facility is caring for patient with a spinal cord injury affecting their sensory and motor reflexes below the waist. Based on the patient's condition, what would be a priority intervention for this patient?

a. Taking care with hot beverages to prevent burns
b. Providing adequate pain relief measures to reduce stress
c. Monitoring for depression related to social isolation
d. Offering meals high in carbohydrates to promote healing

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

. A nurse in the emergency department receives a patient rescued from a building fire. The firefighter giving the handoff report tells the nurse the building collapsed immediately after they removed the patient from the building. The nurse notes the patient is experiencing the alarm phase of the fight-or-flight response. What assessment findings support the nurse's observation? Select all that apply.

a. Rapid breathing
b. Hypotension
c. Restlessness
d. Withdrawn demeanor
e. Tachycardia

. Nurses working in a trauma intensive care unit state they experience a high level of stress. Which stressor are they likely to encounter?

a. Nurse manager support for equitable assignments
b. Health care benefits
c. Debriefings after the death of a patient
d. Incivility by team members or bullying

. A college student visits the school's health center reporting extreme fatigue and slight restlessness. The student states, "Exams are right around the corner, and all I feel like doing is sleeping." There are no abnormal physical assessment findings. How does the nurse best help the student frame their desire to sleep?

a. Asking the student if they are worried about failing exams
b. Telling them they must strive to sleep 7 to 9 hours nightly
c. Evaluating their use of recreational drugs
d. Explaining that some people use sleep as a coping mechanism

. A nurse is interviewing a patient who just received a diagnosis of pancreatic cancer. The patient tells the nurse, "I'm a vegetarian. I'm not the type to get cancer; this must be a mistake." Which defense mechanism is this patient demonstrating?

a. Projection
b. Denial
c. Displacement
d. Repression

. A visiting nurse is assessing a family that includes a young couple and their infant who has cerebral palsy. The nurse notes that the mother is unkempt, the house is untidy, and the mother states she is "so busy with the baby that I don't have time to do anything else." What priority intervention would the nurse set for this family?

a. Arranging to have the infant removed from the home
b. Informing other members of the family of the situation
c. Increasing the number of visits by the visiting nurse
d. Recommending respite care for the parent(s)

. A nurse is teaching a patient who is experiencing stress how to perform a relaxation technique. Which statement by the patient indicates the need for additional teaching?

a. "I must breathe in and out in rhythm."
b. "I should expect my pulse to be faster."
c. "I can expect my muscles to feel less tense."
d. "I will be more relaxed and less aware."

. A nurse in the obstetrics clinic is teaching pregnant patients techniques to manage pain during labor. Which stress reduction activities would be most effective? Select all that apply.

a. Progressive muscle relaxation
b. Meditation
c. Anticipatory socialization
d. Biofeedback
e. Rhythmic breathing
f. Guided imagery

. A nurse at the university health clinic has assessed a student reporting an inability to concentrate and a pounding heart. The student states, "my boyfriend just dumped me out of the blue. They were supposed to be my date at my sister's wedding this weekend. How can I go now?" Which response would the nurse make?

a. "Can you tell me what part of this is most problematic right now?"

b. “What alternatives can you think of at this late date?”
c. “You might start by evaluating your relationship.”
d. “It may be best to not think about this person until after the wedding.”

. A nurse is performing an assessment of a patient who is 8 months’ pregnant. The patient states, “I worry about being able to handle becoming a mother.” The nurse plans interventions for which problem?

a. Poor coping skills
b. Denial about the impending birth
c. Uncertainty and anxiety due to change in role
d. Low self-esteem and fear of parenting

. A parent bringing their toddler for a visit to the pediatric clinic tells the nurse that after work their partner yelled at the child for dropping a fork. Later the patient learned the partner’s supervisor had been angry about the contents of a report that was submitted. The nurse explains it is likely their partner was using which coping mechanism?

a. Denial
b. Sublimation
c. Displacement
d. Dissociation

. A nursing student tells the clinical professor that they hate when they feel anxious before performing new procedures. They state they do not sleep well the night before, feel restless, and have increased alertness. How does the professor best respond to this concern?

a. Suggesting the student seems worried about failing clinical and should seek professional help
b. Stating that we cannot diagnose students, but these symptoms of mild anxiety can aid in learning and growth
c. Suggesting the student is in denial about the need to increase their clinical grade and should meet with the course faculty
d. Asking if they have considered speaking to someone about their panic disorder and recommend a provider

. A nurse in a medical practice has assessed a patient reporting abdominal pain, diarrhea, and anxiety. With no identifiable cause for the pain, which actions to reduce stress would the nurse recommend? Select all that apply.

a. Keeping a diary identifying sources of stress
b. Sleeping 4 hours per night
c. Considering previous strengths and coping mechanisms
d. Asking whom the patient relies on for support
e. Asking if their partner is abusive
f. Assessing for prior psychiatric conditions

. When caring for an older adult in a geriatric practice who seems anxious and inattentive, the nurse plans to discuss stressors particular to the older adult. For which stressors will the nurse assess? Select all that apply.

a. Concern over memory loss
b. Acting as the designated driver for friends
c. Death of spouse last month
d. Inappropriate use of alcohol
e. Successful cataract surgery
f. Recent mobility issues

ANSWERS WITH RATIONALES

. **a, b.** Physiologic effects of stress include changes in appetite and elimination patterns as well as increased pulse and respirations. Using ineffective coping mechanisms, becoming withdrawn and isolated, and exhibiting attention-seeking behaviors are psychological effects of stress.

. **c.** Anticipatory guidance focuses on psychologically preparing a person for an unfamiliar or painful event. When the patient knows what to expect through advanced explanation about discomfort, nausea, or pain and available relief measures, the patient’s anxiety can be reduced. Rhythmic breathing is a relaxation technique, focusing on a pleasant place and breathing slowly in and out is a meditation technique, and focusing on a mental image to reduce responses to stimuli is a guided imagery technique. While these might be addressed, the other options do not reflect anticipatory guidance or focus on postoperative discomfort.

. **a, c, d.** The sympathetic nervous system reacts to stress with the fight-or-flight response. This response causes increased the heart rate, muscle strength, cardiac output, blood glucose levels, and mental alertness. Increased peristalsis is brought on by the parasympathetic nervous system under normal conditions and at rest.

. **c.** The adolescent who is a loner is not meeting a major task (being a part of a peer group) for that level of growth and

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

development.

. **a.** A patient with a damaged neurologic reflex arc has a diminished pain reflex response. This diminished sensation and motor response places the patient at risk for burns. All patients should be provided adequate pain relief, but this is not a priority. Monitoring for depression would be an intervention for this patient but is not related to the damaged neurologic reflex arc. A patient who is immobile should eat a well-balanced diet.

. **a, c, e.** The sympathetic nervous system initiates the fight-or-flight response, preparing the body to fight a stressor or run from it. This phase of the alarm reaction, called the shock phase, is characterized by an increase in energy levels, oxygen intake, cardiac output, blood pressure, and mental alertness. During the second phase, called the countershock phase, there is a reversal of body changes. Hypotension and withdrawn demeanor represent the countershock phase.

. **d.** Incivility encompasses rude or discourteous actions that negatively affect others. Incivility can escalate to bullying, which is defined as repeated, ongoing actions that intend to harm another person. This includes humiliation, offensive speech or actions, or other methods of causing distress. The other options exist in a positive work environment.

. **a.** Fatigue and mild anxiety are often handled without conscious thought through the use of coping mechanisms, such as sleeping. These coping mechanisms are protective behaviors used to decrease stress and anxiety.

. **b.** Denial, a coping mechanism, occurs when a person refuses to acknowledge the presence of a condition that is disturbing. Projection involves attributing thoughts or impulses to someone else. Displacement occurs when a person transfers an emotional reaction from one object or person to another object or person. Repression is used by a person to voluntarily exclude an anxiety-producing event from conscious awareness. This patient is not blocking out the fact that the diagnosis was made, but refusing to believe it.

. **d.** A person providing care at home for a family member for long periods of time often experiences caregiver burden, manifested by chronic fatigue, sleep disorders, and an increased incidence of stress-related illnesses, such as hypertension and heart disease. The nurse could recommend a consultation with a social worker or suggest community resources including possible respite care for the parent(s).

. **b.** No matter what the technique, relaxation involves rhythmic breathing, a slower (not a faster) pulse, reduced muscle tension, and an altered state of consciousness.

. **a, b, e, f.** Relaxation techniques are useful in many situations, including childbirth, and consist of rhythmic breathing and progressive muscle relaxation. Meditation and guided imagery could also be used to distract a patient from the pain of childbirth. Anticipatory socialization helps to prepare people for roles they don't have yet, but aspire to, such as parenthood. Biofeedback is a method of gaining mental control of the autonomic nervous system and thus regulating body responses, such as blood pressure, heart rate, and headaches.

. **a.** Although identifying the problem may be difficult, a solution to a crisis situation is impossible until the problem is identified.

. **c.** The nurse prepares a care plan focusing on anxiety, which can develop in a situational/maturational crises or changes in role status. There is insufficient data to determine whether the patient is demonstrating poor coping, referring to an inability to appraise stressors or use available resources. The patient is not displaying denial, as she is consciously discussing the anxiety rather than attempting to disavow the knowledge or meaning of the impending birth. There is no indication the patient has feelings of worthlessness (poor self-esteem) but rather expresses concern about the role change as she becomes a mother.

. **c.** The nurse can explain that the patient's partner used the coping mechanism displacement, by transferring (displacing) their anger to a "safe" target. Another example is an angry person kicking a chair or slamming a door. The nurse can encourage the patient to discuss this with their partner.

. **b.** The professor can normalize the student's experience by explaining that mild anxiety is present in day-to-day living. It can increase alertness and perceptual fields (e.g., vision and hearing) and motivate learning and growth. Although mild anxiety may interfere with sleep, it also facilitates problem solving. Mild anxiety is often manifested by restlessness and increased questioning. The other options call attention to problems that may not exist.

. **a, c, d.** Keeping a diary of sources of stress can help identify the problem, which is the first step in stress management. The nurse can help the patient identify supports and their strengths. The nurse should recommend sleeping 7 to 9 hours nightly. The nurse would not infer there is a problem of abuse or a psychiatric condition as a cause of their symptoms. Abuse is assessed for routinely, often at the start of the interview, but not in the context of this situation.

. **a, c, d, f.** Stressors of the older adult include declining physical and/or mental capabilities; invasive or health-related tests, examinations, or surgeries (even those with a positive outcome can produce stress, especially related to declining vision); alcohol abuse; diagnosis of chronic illnesses; loss of spouse or significant other; retirement; increased social isolation; loss of independence in living arrangements, driving, or activities of daily living; and chronic pain. The ability to still drive is not considered a stressor.

Loss, Grief, and Dying

Yvonne Malic

Yvonne, a 20-year-old single woman, has just given birth to a baby, 11 weeks premature. The newborn weighs 2 lb 2 oz (1,021 g) and is immediately admitted to the neonatal intensive care unit because of severe respiratory distress. Up until this point, Yvonne had a normal pregnancy and was expecting a healthy baby girl. “I was so happy to be pregnant and I wanted to be a mother so much. But my baby is so tiny! And now the doctors are telling me that she has less than a 50% chance of surviving the next 24 hours.”

Anna Maria Esposita

The Espositas have been married for 19 years and have two children, Jorge, who is 16, and Marita, who is 13. It has been 2 years since Mrs. Esposita was diagnosed with ovarian cancer, and this period has been difficult for the entire family. At present, she is extremely cachexic (thin) and in the end stage of her illness. She initially tried aggressive treatment, and several chemotherapy regimens failed. During her last hospitalization 2 months ago, a decision was made not to continue treatment, and Mrs. Esposita told her family she wanted to die at home.

Manuel Perez

Manuel, 68 years old, moved to a retirement community with his 69-year-old wife 2 months ago. “We were looking forward to traveling and playing lots of golf. But she had this stroke, and now she has massive irreversible brain damage.” Mr. Perez is sitting at his wife’s bedside, holding her hand, and crying. “The doctors are asking me if I want to continue treatments that are keeping her alive. They mentioned donating her organs. I don’t know what to do. We never talked about what we would want.”

Learning Outcomes

After completing the chapter, you will be able to accomplish the following:

. Explain the concepts of loss and grieving, including types of loss and grief reactions.
. Describe the signs of impending death.
. Compare and contrast the five emotional stages of dying defined by Kübler-Ross.
. Identify ethical and legal issues in end-of-life care, including advance directives, physician orders, assisted suicide/medically assisted dying, and euthanasia.
. Articulate and defend a personal response to a patient’s plea, “Please help me die.”
. Explain six factors that affect loss, grief, and dying.
. Describe physiologic, psychological, and spiritual care of a seriously ill and/or dying patient and family.
. Use the nursing process to plan and implement care for seriously ill and/or dying patients and their families.
. Outline nursing interventions when providing postmortem care.
. Discuss the role of the nurse in caring for the family/caregivers of a dying patient.

active euthanasia

The potential for loss, grief, and death exists at any stage of life. This is especially true for people experiencing altered health and for members of their families. A wide variety of losses may occur, including loss of a body part or function, loss of the ability to care for oneself or to perform valued family or work roles, and death, which may be the most difficult loss of all. Death may be as difficult for health care professionals as it is for surviving family members. The goals of nursing include promoting a respectful and peaceful death through compassionate palliative care and facilitating the patient's and family's coping with disability and death. The nurse is often the person providing support and care when loss or death occurs. To provide effective care, the nurse must have accepted their own feelings about death and understood the stages of grieving and dying. Care of the seriously ill and dying became increasingly challenging during the COVID-19 pandemic when many critically ill patients were deprived of the comfort of family because of revised visitation policies. Nurses not only provided the physical care that seriously ill patients needed but used smartphones and tablets to facilitate communication between patients and their families. All too often it was only the nurse holding the hand of a hospitalized dying patient. For an example, see the Reflective Practice box on pages 1794–1795.

CONCEPTS OF LOSS AND GRIEF

The types of loss, as well as the varied responses to a loss, are important concepts when planning and implementing nursing interventions to facilitate effective coping and adaptation.

Loss

Loss occurs when a valued person, object, or situation is changed or becomes inaccessible such that its value is diminished or removed. There are several types of loss, all of which everyone may experience at some time. **Actual loss** can be recognized by others as well as by the person sustaining the loss—for example, loss of a limb, a child, a valued object such as money, and a job. **Perceived loss**, such as loss of youth, financial independence, or a valued environment, is experienced by the person but is intangible to others. Directly related to actual and perceived loss are physical and psychological loss. A person who loses an arm in an automobile crash suffers from both the physical loss of the arm and the psychological loss that may be caused by an altered self-image and the inability to return to their occupation or other activities. These losses are simultaneously physical, psychological, and actual. A person who is scarred but does not lose a limb may suffer a perceived and psychological loss of self-image.

Remember **Mr. Perez**, whose wife has brain damage from a recent stroke. The nurse could use knowledge of the types of loss to help Mr. Perez deal with all the recent changes in his life, including the loss of his wife as an active partner.

Other types of loss are maturational loss, situational loss, and anticipatory loss. Maturational loss is experienced as a result of natural developmental processes. As examples, a first child may experience a loss of status when a sibling is born, and the parent of a single child may experience a sense of loss when the child begins school. Situational loss is experienced as a result of an unpredictable event, including traumatic injury, disease, death, or national disaster. **Anticipatory loss** occurs when a person displays loss and grief behaviors for a loss that has yet to take place (Fig. 44-1 on page 1795). Anticipatory loss is often seen in the families of patients with serious and life-threatening illnesses and may lessen the effect of the actual loss of the family member.

Think back to **Yvonne Malic**, the 20-year-old single mother of the premature neonate described at the beginning of the chapter. The nurse could use knowledge of anticipatory loss to assist Yvonne in coping with the seriousness of her neonate's condition.

QSEN Reflective Practice: Cultivating QSEN Competencies

CHALLENGE TO ETHICAL AND LEGAL SKILLS

Anna Maria Giordano was a 49-year-old attorney who had recently suffered a major cerebral hemorrhage. I came in contact with Ms. Giordano on one of my off-site clinical rotations when I accompanied a social worker for a day at a large medical center. According to most of the nurses and physicians, and the documentation in her chart, her prognosis looked very poor. Due to the fact that she was a lawyer, her advance directives were very clear, appearing to say exactly what she wanted. In essence, her advance directives stated that if she was in a comatose condition and that it appeared as if there was no hope for recovery, she did not want life-sustaining treatment. Although testing did not reveal brain death, almost all the health care providers agreed that her condition had little to no hope for improvement. However, one neurosurgeon felt that her condition was improving, with hopes for her recovery; therefore, he had no intention of stopping the life-sustaining treatment. Her family members from Boston had come earlier in the week to discuss treatment options and were given two points of view by two different health care providers. Upon hearing the determination of a poor prognosis, seeing no improvement in the patient's condition over the past few weeks, and being familiar with her expressed preferences in the advance directive, I felt certain that she would not want life-sustaining treatment continued.

Thinking Outside the Box: Possible Courses of Action

- Ignore the entire situation: It didn't entirely concern me, since I was only observing as a nursing student for 1 day.
- Talk to the social worker about what I thought was stated in the advance directives, and ask why it wasn't being followed.
- Challenge the doctor as to why he was telling the family that the patient was improving when her assessments for the past 3 weeks had shown no improvement.

Evaluating a Good Outcome: How Do I Define Success?

- The patient is properly diagnosed and her wishes from her advance directives are followed as clearly as they are stated.
- Since the patient is unable to speak, her power of attorney is able to convey what the patient would want.
- The family and the patient's power of attorney are fully informed about the patient's condition so that they can make an educated decision based on what the patient would want.
- My personal and professional integrity are affirmed.

Personal Learning: Here's to the Future!

I chose to talk to the social worker about the patient's advance directives. The social worker was very aware of the situation; she explained that, in the past, this neurosurgeon had given other patients' families more optimistic views of their situations and had refused to stop life-sustaining treatment. The social worker explained that she was in the process of bringing this issue to an ethics committee to discuss the situation and hoped that something would be resolved. She also explained that advance directives are often difficult to follow precisely. If the patient is unable to communicate, then the person designated with power of attorney takes over and tries their best to do what the patient would want. In such situations, decision making can become very subjective. Therefore, following the advance directives is not as simple

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

as one would think it would be.

Although my actions were not extraordinary in this situation, I felt that I learned quite a bit about advance directives, especially trying to honor the patient's and family's wishes. I had learned about advance directives in the past in my previous classes. However, this was the first time I had ever had to deal with one in actual practice. I was able to see how difficult it can be to make such an important decision. I was impressed by the way the social worker was handling the case; I only hope that I would act in a similar fashion if I were ever faced with a situation like this in the future.

Kathryn Southerton, Georgetown University

QSEN SELF-REFLECTION ON QUALITY AND SAFETY COMPETENCIES DEVELOPING KNOWLEDGE, SKILLS, AND ATTITUDES FOR CONTINUOUS IMPROVEMENT

How do you think you would respond in a similar situation? Why? Are there any factors that might affect your response? If so, explain what these factors are and their possible effect. Do you agree with the criteria that the nursing student used to evaluate a successful outcome? Why or why not? What *knowledge, skills,* and *attitudes* do you need to develop to continuously improve the quality and safety of care for patients like Ms. Giordano? Was professional integrity affirmed? Explain.

Patient-Centered Care: How can you deliver thoughtful, person-centered care for patients with whom you cannot communicate? How can you best communicate empathy and respect for this patient and her family?

Teamwork and Collaboration/Quality Improvement: What do you think might be influencing the neurosurgeon's refusal to end the life-sustaining treatment? How would you respond to this neurosurgeon? What does this tell you about yourself and about the adequacy of your skills for professional practice? The neurosurgeon is in what stage of grief, in your opinion? The nursing student? The social worker? What communication and interpersonal skills do you need to improve to ensure that you function as an effective member of the patient care team and are able to obtain assistance when needed? What does quality care for Ms. Giordano "look like"?

Safety/Evidence-Based Practice: What does the evidence point to as "best practice" for Ms. Giordano? What safety needs does Ms. Giordano have and how can you meet them? Have you ever been involved in a situation involving an advance directive? If so, were the patient's wishes followed? If not, why not?

Informatics: Can you identify the essential information that must be available in Ms. Giordano's electronic record to support safe patient care and coordination of care? Can you think of other ways to respond to or approach the situation? What else might the nursing student have done to ensure a successful outcome?

Grief

Grief is an internal emotional reaction to loss. It occurs with loss caused by separation or by death. For example, many people who divorce experience grief. Loss of a body part, job, house, or pet may also cause grief. Normal expressions of grief may be physical (crying, headaches, difficulty sleeping, fatigue), emotional (feelings of sadness and yearning), social (feeling detached from others and isolating yourself from social contact), and spiritual (questioning the reason for your loss, the purpose of pain and suffering, the purpose of life and the meaning of death). **Mourning** is the actions and expressions of that grief, including the symbols and ceremonies (e.g., a funeral or final celebration of life) that make up the outward expressions of grief. **Bereavement** is a state of grieving due to loss of a loved one.

Grief Reactions

Grief reactions and reactions to dying are similar. The stages of these reactions overlap and vary among people (see Factors That Affect Grief and Dying, later in this chapter). One person may skip a reaction stage, whereas another may repeat an earlier stage. Each person is different, and patients and family members may be at different reaction stages. Several theories explain the stages of grief reactions and reactions to dying; two discussed here are by Engel and Kübler-Ross. More important than the actual stages of any given grief reaction is the idea that grief is a process that varies from person to person.

FIGURE 44-1. A terminally ill patient's husband begins the grieving process.

Engel (1964) was among the first to define stages of grief. Engel's six stages are (1) shock and disbelief, (2) developing awareness, (3) restitution, (4) resolving the loss, (5) idealization, and (6) outcome. Shock and disbelief are usually defined as refusal to accept the fact of loss, followed by a stunned or numb response: "No, not me." Developing awareness is characterized by physical and emotional responses such as anger, feeling empty, and crying: "Why me?" Restitution involves the rituals surrounding loss; with death, it includes religious, cultural, or social expressions of mourning, such as funeral services. Resolving the loss involves dealing with the void left by the loss. Idealization is the exaggeration of the good qualities of the person or object, followed by acceptance of the loss and a lessened need to focus on it. Outcome, the final resolution of the grief process, includes dealing with loss as a common life occurrence.

Kübler-Ross (1969), a pioneer in the study of grief and death reactions, defined five stages of reaction similar to Engel's. These stages—(1) denial and isolation, (2) anger, (3) bargaining, (4) depression, and (5) acceptance—are discussed later in the chapter.

Dysfunctional Grief

Dysfunctional grief is abnormal or distorted; it may be either unresolved or inhibited. In unresolved grief, a person may have trouble expressing feelings of loss or may deny them; unresolved grief also describes a state of bereavement that extends over a lengthy period. With inhibited grief, a person suppresses feelings of grief and may instead manifest somatic (body) symptoms, such as abdominal pain or heart palpitations.

DYING AND DEATH

Death may occur suddenly as a result of an accident, injury, or illness or it may occur after a prolonged experience of a debilitating disease such as cancer, acquired immunodeficiency syndrome (AIDS), or Alzheimer's disease.

Definitions of Death

The accurate definition of death has proven difficult over time, as technologic advances, such as cardiopulmonary resuscitation, have been able to restore lost functions and "bring a person back to life." The Uniform Determination of Death Act (1981) provides a legal definition of **death** as either (1) irreversible cessation of circulatory and respiratory functions, or (2) irreversible cessation of all functions of the entire brain, including the brainstem. A determination of death must be made in accordance with accepted medical standards.

A Harvard University Medical School committee later added that the irreversible loss of brain function, accompanied by the more traditional signs, should be the definitive definition of death. These "Harvard criteria" are generally accepted with the understanding that errors in certification of death could occur in conditions that may not permanently suspend life processes, such as hypothermia (extreme cold), drug or metabolic intoxication, or circulatory shock. In addition, special attention must be paid when establishing death in a child younger than age 5 years.

Most protocols for establishing death require two separate clinical examinations. The medical criteria used to certify a death are as follows:

- Breathing cessation
- No response to deep painful stimuli
- Lack of reflexes (such as the gag or corneal reflex) and spontaneous movement
- Flat encephalogram (brain waves)

You may hear clinicians refer to heart–lung death (cessation of the apical pulse, respirations, and blood pressure) and cerebral or higher brain death (when the cerebral cortex is irreversibly destroyed). These clinical signs may be further

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

confirmed by an electroencephalogram or cerebral blood flow study. See Milliken and Uveges (2020) for a discussion of brain death, its history, updates, and implications for nurses.

Signs of Impending Death

The clinical signs of impending or approaching death include:

- Difficulty talking or swallowing
- Nausea, flatus, and abdominal distention
- Urinary or bowel incontinence or constipation
- Loss of movement, sensation, and reflexes
- Decreasing body temperature with cold or clammy skin
- Weak, slow, or irregular pulse
- Decreasing blood pressure
- Noisy, irregular, or Cheyne–Stokes respirations
- Restlessness or agitation
- Cooling, mottling, and cyanosis of the extremities and dependent areas

As death nears, the patient may have a decreased level of consciousness or agitated delirium. Although decreased consciousness and agitation are both normal at the end of life, they are very distressing to the patient's family. It is important for nurses to prepare family members when death is imminent and to determine if they are more comfortable being alone with a dying loved one or supported by a nurse or other member of the professional caregiving team.

A "Good Death"

A good death is one that allows a person to die on their own terms, relatively free of pain, and with dignity. It is free from avoidable distress and suffering for patients, families, and caregivers; in general accord with patients' families' wishes; and reasonably consistent with clinical, cultural, and ethical standards (Institute of Medicine [IOM], 1997). The characteristics of a good death vary for each patient; several important factors include control of symptoms, preparation for death, opportunity for the person to have a sense of completion of their life, and a good relationship with health care professionals. The indicators for care that promotes a good death are listed in Box 44-1; although they were developed by the American Geriatrics Society (AGS) Ethics Committee (2007), they apply to people of all ages. Nurses play a critical role in focusing the health care team's attention on meeting the needs of dying people and their families. Broden et al. (2020) define what a "good death" looks like in the pediatric intensive care unit (ICU).

Box 44-1 Providing Care to Facilitate a Good Death

Although death occurs at any age, the probability of death increases as a person grows older. These selected statements from the American Geriatrics Society Ethics Committee provide guidance for all health care providers in providing excellent care for dying patients of any age.

- The care of the dying patient should be guided by the values and preferences of the individual patient. Independence and dignity are central issues for many dying patients, particularly in older adults. Maintaining control and not being a burden can also be relevant concerns.
- Palliative care of dying patients is an interdisciplinary undertaking that attends to the needs of both patient and family.
- Care for dying patients should focus on the relief of symptoms, not limited to pain, and should use both pharmacologic and nonpharmacologic means.
- Physicians and other health care professionals, at all levels of training, should receive in-depth, insightful, and culturally sensitive instruction in the optimal care of dying patients.
- Adequate funding for research on the optimal care of dying patients is essential to improving end-of-life care.

Source: From American Geriatrics Society (AGS) Ethics Committee. (2007). *The Care of Dying Patients: A Position Statement from the American Geriatrics Society*. *43*(5) Author; with permission from John Wiley and Sons.

In 2015, the IOM (now the National Academy of Sciences, Engineering, and Medicine) issued a report, *Dying in America: Improving quality and honoring individual preferences near the end of life*. The IOM recommended that comprehensive care should:

- Be seamless, high quality, integrated, patient centered, family oriented, and consistently accessible around the clock.
- Consider the evolving physical, emotional, social, and spiritual needs of individuals approaching the end of life as well as those of their family and caregivers.
- Be competently delivered by professionals with appropriate expertise and training.
- Include coordinated, efficient, and interoperable information transfer across all providers and all settings.
- Be consistent with individuals' values, goals, and informed preferences.

Responses to Dying and Death

People have varying attitudes about death. Increasing numbers are choosing to die at home surrounded by loved ones. Others die alone or in ICUs surrounded by health care professionals and technologic equipment. Although each person reacts to the knowledge of impending death or to loss in their own way, there are similarities in the psychosocial responses to the situation. Kübler-Ross (1969) studied the emotional responses to death and dying in depth, and nursing and other helping professions have used her findings extensively.

The stages of dying, much like the stages of grief, may overlap, and the duration of any stage may range from as little as a few hours to as long as months. The process varies from person to person. Some people may be in one stage for such a short time that it seems as if they skipped that stage. Sometimes a person returns to a previous stage. According to Kübler-Ross, the five stages of dying, with common reactions, are:

. *Denial:* The patient denies the reality of death and may repress what is discussed. The patient may think, "They made a mistake in the diagnosis. Maybe they mixed up my records with someone else's."
. *Anger:* The patient expresses rage and hostility and adopts a "why me?" attitude: "Why me? I quit smoking and I watched what I ate. Why did this happen to me?"
. *Bargaining:* The patient tries to barter for more time: "If I can just make it to my son's graduation, I'll be satisfied. Just let me live until then." Many patients put their personal affairs in order, make wills, and fulfill last wishes, such as trips, visiting relatives, and so forth. It is important to meet these wishes, if possible, because bargaining helps patients move into later stages of dying.
. *Depression:* The patient goes through a period of grief before death. The grief is often characterized by crying and not speaking much: "I waited all these years to see my daughter get married. And now I may not be here to see her walk down the aisle. I can't bear the thought of not being there for the wedding—and of not seeing my grandchildren."
. *Acceptance:* When the stage of acceptance is reached, the patient feels tranquil. The patient has accepted the reality of death and is prepared to die. The patient may think, "I've tied up all the loose ends: made the will, made arrangements for my daughter to live with her grandparents. Now I can go in peace knowing everyone will be fine."

Terminal Illness

In the case of a **terminal illness**, an illness in which death is expected within a limited period of time, the health care provider is usually responsible for deciding what, when, and how the patient should be told. The nurse, along with members of the clergy and other health care professionals, may be involved with these decisions and in discussing the condition with the patient. Most patients want to know their diagnosis and prognosis as soon as possible so that they can begin appropriate planning and take care of business and personal affairs. It is critical for terminally ill patients and their families to have some sense of how the disease is most likely to progress and what this will mean for the patient. All who are involved with the patient's care should know exactly what the patient and the family have been told; members of the patient's health care team need to communicate among themselves. *Cultural influences may dictate how much information is desired and which family members are to be informed.* For example, in some cultures it is still the norm that the patient's family—not the patient—is told the diagnosis and prognosis. Since this is now changing, nurses must check local practice standards and policies as well as the preferences of individual patients and families. You can never go wrong if you ask patients how much information they would like about their medical condition. "We will be learning things about your health as a result of the diagnostic testing we are doing. Do you want to receive this information or would you prefer that we give this to a family member or someone else of your choosing?"

Effect on the Patient

Many patients realize without being told that they have a terminal illness, picking up this knowledge from nonverbal communication by their families and by health care professionals. Patients must be allowed to go through the stages of the grieving process and be supported in their decision making. Competent patients have the right to consent to or refuse any and all indicated medical treatment—even life-sustaining treatment—and should be made aware of this right. In the past, patients and family members complained about receiving care they did not want and of not being allowed to die. In today's climate of cost-conscious decision making, some patients and family members are complaining that they are being denied costly life-sustaining treatment because of inadequate personal funds or insurance or because they are deemed a poor "investment" of scarce resources. Remember that a patient's wishes should, if possible, be followed. Box 44-2 (on page 1798) lists the rights of people who are dying.

Box 44-2 **The Dying Person's Bill of Rights**

I have the right to be treated as a living human being until I die.
I have the right to maintain a sense of hopefulness, however changing its focus may be.
I have the right to be cared for by those who can maintain a sense of hopefulness, however changing this might be.
I have the right to express my feelings and emotions about my approaching death in my own way.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

I have the right to participate in decisions concerning my care.
I have the right to expect continuing medical and nursing attention even though “cure” goals must be changed to “comfort” goals.
I have the right not to die alone.
I have the right to be free from pain.
I have the right to have my questions answered honestly.
I have the right not to be deceived.
I have the right to have help from and for my family in accepting my death.
I have the right to die in peace and dignity.
I have a right to retain my individuality and not be judged for my decisions, which may be contrary to beliefs of others.
I have the right to discuss and enlarge my religious and/or spiritual experiences, whatever these may mean to others.
I have the right to expect that the sanctity of the human body will be respected after death.
I have the right to be cared for by caring, sensitive, knowledgeable people who will attempt to understand my needs and will be able to gain some satisfaction in helping me face my death.

Source: The Bill of Rights was created at a workshop on ‘The Terminally Ill Patient and the Helping Persons,’ in Lansing, Michigan, sponsored by the Southwestern Michigan Inservice Education Council and conducted by Amelia J. Barbus, associate professor of nursing, Wayne State University, Detroit.

Effect on the Family

Whenever possible, with the patient’s permission, encourage the family and significant others of terminally ill patients to participate in planning the patient’s care. Orsatti and Colbert (2020) offer helpful advice when siblings are conflicted about a parent’s end-of-life care. Health care personnel should be available to discuss the patient’s condition with family members and should offer support and care as the family begins the grieving process (Fig. 44-2). The family may want to make arrangements with the patient for funeral or memorial services, depending on which stage of grief both the patient and the family members are in.

Palliative Care and Hospice

Palliative care involves taking care of the whole person—body, mind, and spirit; heart and soul. It views dying as something natural and personal. The goal of palliative care is to give patients with life-threatening illnesses the best quality of life they can have by the aggressive management of symptoms. In January 2016, The American Nurses Association (ANA) and the Hospice and Palliative Nurses Association (HPNA) partnered to develop *Call for Action: Nurses Lead and Transform Palliative Care*. They concluded that seriously ill and injured patients, families, and communities should receive quality palliative care in all care settings. This was to be achieved by the delivery of primary palliative care nursing by every nurse regardless of setting. Since nurses are frequently the source of palliative care consults, you will want to be familiar with palliative care screening tools to identify patients for whom palliative care will be helpful (Martz et al., 2020; Venis & Dodek, 2020).

FIGURE 44-2. A nurse offers support to a patient’s grieving spouse.

As you begin your clinical practice, you will want to be intentional about developing the knowledge, skills, and

attitudes necessary to provide excellent palliative care. Roy (2020) answers frequently asked questions about palliative care. Be sure to check out the Clinical Practice Guidelines for Quality Palliative Care, published by the National Consensus Project for Quality Palliative Care, available online at http://keyweb24.com/nchpc/wp-content/uploads/2017/04/NCP_Clinical_Practice_Guidelines_3rd_Edition.pdf. Also of interest, in 2017, the ANA issued a call for public comment on a position statement, The Ethical Responsibility to Manage Pain and Suffering. See Chapter 36 for further information.

Hospice care is care provided for people with limited life expectancy, often in the home. When considering whether a patient is a candidate for hospice care, ask yourself, "Would I be surprised if this person died within the next 6 months?" Indicators for hospice referral (Puffenbarger, 2014) include:

- Poor performance status
- Declining cognitive status
- Advanced age
- Poor nutritional intake
- Pressure injuries
- Comorbidities
- Previous hospital admissions for acute decompensation

While hospice care focuses on the needs of the dying, palliative care is appropriate across the spectrum of disease and illness. Both palliative care and hospice care are discussed in Chapter 11. Also see the National Hospice and Palliative Care Organization's (2019) "Palliative care or hospice? The right service at the right time for seriously ill individuals" available at https://www.nhpco.org/wp-content/uploads/2019/04/PalliativeCare_VS_Hospice.pdf.

Established in 1986, the HPNA (www.hpna.org) is the nation's largest and oldest professional organization dedicated to promoting excellence in palliative nursing care. Among its aims are assisting members of the nursing team with ensuring quality nursing care delivery, managing complex symptoms along with grief and bereavement, and having difficult conversations.

Ethical and Legal Dimensions

Multiple treatment options and sophisticated life support technologies may make it difficult to draw the line between promoting life and needlessly prolonging the dying process. This complicates health care decision making for patients and health care professionals alike. Patients have a legally and morally protected right to consent to or refuse medical therapies. Legal foundations for the patient's freedom to choose include the common law right of self-determination and the constitutionally supported right of privacy (discussed in Chapters 6 and 7). Discussions about legalizing physician-assisted suicide and physician-administered lethal injections (euthanasia) pose new ethical challenges. As patients and families struggle with end-of-life treatment decisions, they are increasingly looking to nurses for information, advice, and support. It is important for you to clarify your own beliefs about suicide and euthanasia before attempting to counsel patients and the public. Take time to work through your answers to the questions in Box 44-4 on page 1804. Articles addressing the moral distress nurses experience when helping patients and their families make these decisions include the following: Altaker et al. (2018), Esfahani et al. (2020), Wolf et al. (2019).

Advance Care Planning

Decisions about health care are becoming increasingly complex. Patients, family members, and health care professionals are voicing frustration as they grapple with complex decisions about prolonging life. Some of the most difficult cases involve patients who are no longer able (competent) to indicate their treatment preferences. **Advance care planning (ACP)** is a process of planning for future care in the event a person becomes unable to make their own decisions. Because such events can occur in healthy people as well as in older adults or patients with serious illnesses, ACP is recommended for all adults, whatever their age or health status (Izumi, 2017, p. 57).

Two kinds of written **advance directives**—a *living will* and a *durable power of attorney for health care*—can minimize difficulties by allowing people to state in advance what their choices would be for health care should certain circumstances develop. Living wills provide specific instructions about the kinds of health care that should be provided or foregone in particular situations. A durable power of attorney for health care appoints an agent the person trusts to make decisions in the event of subsequent incapacity. A combination directive is illustrated in Figure 44-3 (on pages 1800–1801). The organization Aging with Dignity offers a popular living will titled *Five Wishes* (available at https://www.agingwithdignity.org) that allows people to specify the following:

- The person I want to make care decisions for me when I can't
- The kind of medical treatment I want or don't want
- How comfortable I want to be
- How I want people to treat me
- What I want my loved ones to know

Many methods have been suggested to ensure that adult patients have an opportunity to learn about and use advance directives to indicate their wishes about life-prolonging treatment and to appoint surrogate decision makers should they

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

lose decision-making capacity. Nurses play an important role in facilitating this dialogue. In the United States, the Patient Self-Determination Act of 1990 requires all hospitals to inform patients about advance directives.

Legal Alert

Because the status of advance directives varies from state to state, nurses must be familiar with federal and state laws concerning these directives.

Nurses can also be instrumental in developing institutional policies that ensure that patients on admission are encouraged to talk with family, significant others, and health care professionals about their treatment preferences. Important resources for ACP include the National Hospice and Palliative Care Organization's CaringInfo program (www.caringinfo.org); the American Bar Association's Tool Kit for Health Care Advance Planning (https://www.americanbar.org/groups/law_aging/resources/health_care_decision_making/consumer_s_toolkit_for_health and The Conversation Project (http://theconversationproject.org).

A Physician Order for Life-Sustaining Treatment form, or **POLST form**, is a medical order indicating a patient's wishes regarding treatments commonly used in a medical crisis. Because it is a medical order, a POLST form must be completed and signed by a health care professional and cannot be filled out by a patient. These forms are always completed in close consultation with the patient to ensure that the patient's values and goals of care are accurately represented. These brightly colored forms (see the POLST website, www.polst.org) always remain with the patient, regardless of whether the patient is in the hospital, at home, or in a long-term care facility. See Box 44-3 for a description of the differences between an advance directive and POLST form. POLST forms are not available in every state. In some states, such as Maryland, they are called Medical Orders for Life-Sustaining Treatment forms, or **MOLST forms**.

D.C., Maryland and Virginia

ADVANCE DIRECTIVE

My Durable Power of Attorney for Health Care, Living Will and Other Wishes

I, _____ , write this document as a directive regarding my medical care.

Put the initials of your name by the choices you want.

PART 1. MY DURABLE POWER OF ATTORNEY FOR HEALTH CARE.

_____ I appoint this person to make decisions about my medical care if there ever comes a time when I cannot make those decisions myself:

NAME _____ PHONE HOME _____ WORK _____

ADDRESS _____

_____

If the person above cannot or will not make decisions for me, I appoint this person:

NAME _____ PHONE HOME _____ WORK _____

ADDRESS _____

_____

_____ I have not appointed anyone to make health care decisions for me in this or any other document.

I want the person I have appointed, my doctors, my family, and others to be guided by the decisions I have made below:

PART 2. MY LIVING WILL.

These are my wishes for my future medical care if there ever comes a time when I can't make these decisions for myself.

A. **These are my wishes if I have a *terminal condition:***
Life-Sustaining Treatments

_____ I do not want life-sustaining treatments (including CPR) started. If life-sustaining treatments are started, I want them stopped.
_____ I want life-sustaining treatments that my doctors think are best for me.

_____ Other wishes: _____

Artificial Nutrition and Hydration

_____ I do not want artificial nutrition and hydration started if it would be the main treatment keeping me alive. If artificial nutrition and hydration is started, I want it stopped.
_____ I want artificial nutrition and hydration even if it is the main treatment keeping me alive.

_____ Other wishes: _____

Comfort Care

_____ I want to be kept as comfortable and free of pain as possible, even if such care prolongs my dying or shortens my life.

_____ Other wishes: _____

B. **These are my wishes if I am ever in a *persistent vegetative state:***

Life-Sustaining Treatments

_____ I do not want life-sustaining treatments (including CPR) started. If life-sustaining treatments are started, I want them stopped.
_____ I want life-sustaining treatments that my doctors think are best for me.

_____ Other wishes: _____

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Artificial Nutrition and Hydration

_____ I do not want artificial nutrition and hydration started if it would be the main treatment keeping me alive.
If artificial nutrition and hydration is started, I want it stopped.
_____ I want artificial nutrition and hydration even if it is the main treatment keeping me alive.

_____ Other wishes: _____

Comfort Care

_____ I want to be kept as comfortable as possible, even if such care prolongs my dying or shortens my life

_____ Other wishes: _____

C. **Other Direction**

You have the right to be involved in all decisions about your medical care, even those parts not dealing with terminal conditions or persistent vegetative states. If you have wishes not covered in other parts of this document, please indicate them here.

_____

_____

PART 3. OTHER WISHES.

A. **Organ Donation**

_____ I do not wish to donate any of my organs or tissues.
_____ I want to donate all of my organs and tissues.
_____ I only want to donate these organs and tissues: _____

_____ Other wishes: _____

Autopsy

_____ I do not want an autopsy.
_____ I agree to an autopsy if my doctors wish it.

_____ Other wishes: _____

If you wish to say more about any of the above choices, or if you have any other statements to make about your medical care, you may do so on a separate sheet of paper. If you do so, put here the number of pages you are adding: _____

PART 4. SIGNATURES.

You and two witnesses must sign this document for it to be legal.

A. **Your Signature**

By my signature below I show that I understand the purpose and the effect of this document.

SIGNATURE _____ DATE _____

ADDRESS _____

B. **Your Witnesses' Signatures**

I believe the person who has signed this advance directive to be of sound mind, that he/she signed or acknowledged this advance directive in my presence, and that he/she appears not to be acting under pressure, duress, fraud or undue influence. I am not related to the person making this advance directive by blood, marriage or adoption, nor, to the best of my knowledge, am I named in his/her will. I am not the person appointed in this advance directive. I am not a health care provider or an employee of health care provider who is now, or has been in the past, responsible for the care of the person making this advance directive.

Witness #1

SIGNATURE _____ DATE _____

ADDRESS _____

Witness #2

SIGNATURE _____ DATE _____

ADDRESS _____

FIGURE 44-3. Example of an advance directive. (*Source:* Used with permission of District of Columbia Hospital Association, Washington, DC.)

Box 44-3 Advance Directive Versus POLST Form: Primary Differences

Advance Directive

- For anyone 18 and older
- Provides instructions for **future** treatment
- Appoints a Health Care Representative
- Does not guide Emergency Medical Personnel
- Guides inpatient treatment decisions when made available

Physician Order for Life-Sustaining Treatment (POLST) Form

- For persons with serious illness—at any age
- Provides medical orders for **current** treatment
- Guides actions by Emergency Medical Personnel when made available
- Guides inpatient treatment decisions when made available

Allow Natural Death, Do-Not-Resuscitate, or No-Code Order

To prevent the improper use of cardiopulmonary resuscitation, which is designed to prevent unexpected death, some health care providers write **Do-Not-Resuscitate (DNR) order**, or No Code, on the medical record of a patient if the patient or surrogate has expressed a wish that there be no attempts to resuscitate the patient. A DNR order means that no attempts are to be made to resuscitate a patient whose breathing or heart stops. Some facilities use the term **Allow Natural Death (AND) order** instead of DNR because it is easier for families to authorize doing something positive rather than preventing something (i.e., a resuscitative effort) that is usually perceived to be helpful. You may also see a Do-Not-Intubate (DNI) order. Many health care providers are reluctant to write these orders, however, especially when the issue is a source of conflict between the patient and family or between individual family members. See the accompanying Research in Nursing box.

In some cases, a health care provider who believes the patient will not benefit from resuscitative measures may indicate verbally to the nurse that only a Slow Code (or "Show Code") should be called—that is, in the case of cardiopulmonary or respiratory arrest, calling a code and resuscitating the patient are to be delayed until these measures will be ineffectual. Many health care institutions have policies forbidding this, and a nurse could be charged with negligence in the event of a Slow Code and resulting patient death. Be sure to check your facility's policies.

The standard of care still obligates health care professionals to attempt resuscitation if a patient's breathing or heart stops (cardiopulmonary arrest) and there is no AND or DNR order to the contrary. For this reason, nurses must clarify a patient's code status if the probable benefits of resuscitation are negligible or if the nurse has reason to believe a patient would not want to be resuscitated. Many states now allow patients living at home to craft POLST/MOLST orders that allow emergency medical technicians called to the home in the event of cardiopulmonary arrest to respect the patient's wishes not to be resuscitated.

Research in Nursing

Bridging the Gap to Evidence-Based Practice

Interpreting Do-Not-Resuscitate Orders

Misinterpretations of do-not-resuscitate (DNR) orders (including the belief that it means "do not treat") are common but there is a paucity of research concerning nurses' perspectives on DNR orders.

Related Research

Kelly, P. A., Baker, K. A., Hodges, K. M., Vuong, E. Y., Lee, J. C., & Lockwood, S. W. (2021). Nurses' perspectives on caring for patients with Do-Not-Resuscitate orders. *American Journal of Nursing, 121*(1), 26–36.

This mixed-methods study was designed to explore nurses' perspectives on the meaning and interpretation of DNR orders in relation to caring for hospitalized adults with such orders. Most of the 35 nurses who responded to the case study survey chose to prioritize palliative care, despite no indication that any plan of care was in place. Analysis of interview data revealed this overarching theme: varying interpretations of DNR orders among nurses were common, resulting in unintended consequences. Participants also reported perceived variances among health care team members, patients, and family members. Such misinterpretation resulted in shifts in care, varying responses to deteriorating status, tension, and differences in role expectations for health care team members.

Comfort Measures Only and Other Special Orders

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

When a discussion is taking place about resuscitation, it is also appropriate to question the use of other life-sustaining interventions, such as dialysis, ventilatory support, artificial nutrition and hydration, blood transfusions, antibiotics and other medications, and surgery. Whereas some patients may want aggressive life-sustaining treatment and such treatment may be medically beneficial, other patients may be at a point in their illness at which they choose to terminate all life-sustaining measures and allow the disease to progress naturally to death. There is no moral obligation to initiate or continue the use of life-sustaining treatment that is minimally effective or is a burden. However, laws may place constraints on those who decide to withhold or withdraw life-sustaining treatment for incompetent patients and, in some states, for patients who are pregnant. Nurses should know pertinent federal and state laws and the policies in their institution or facility concerning the withholding or withdrawing of life-sustaining treatment. Nurses should also be familiar with the forms used to indicate patient preferences about end-of-life care.

Patients or their surrogates may request a **Comfort Measures Only order**, which indicates that the goal of treatment is a comfortable, dignified death and that further life-sustaining measures are no longer indicated. A Do-Not-Hospitalize order is often used for patients in long-term care and other residential settings who have elected not to be hospitalized for further aggressive treatment.

Terminal Weaning

Terminal weaning is the gradual withdrawal of mechanical ventilation from a patient with a terminal illness or an irreversible condition with a poor prognosis. In some cases, competent patients wish their ventilatory support to be ended; more often, the surrogate decision makers for an incompetent patient determine that continued ventilatory support is futile. Although it may be expected that a patient will not survive the weaning, death is never a certain outcome, and it is not unusual for a patient to begin spontaneous respirations once ventilatory support is withdrawn and live for several hours to several days. Competent patients and family members should be prepared for all possibilities. A nurse's role in terminal weaning is to participate in the decision-making process by offering helpful information about the benefits and burdens of continued ventilation and a description of what to expect if terminal weaning is initiated. Supporting the patient's family, monitoring symptoms, and administering medications as available to manage symptoms are critical nursing responsibilities. The goal should be the minimum dose of medication necessary to manage the symptoms. The goal is not sedation. Unfortunately, many facilities and institutions do not have policies covering this issue. Nurses involved in terminal weaning should consult the literature and be familiar with the latest research.

Voluntary Stopping of Eating and Drinking (VSED)

As seriously ill, competent patients make end-of-life treatment decisions, they may also choose to refuse food and fluid with the intention of hastening death. It is important to distinguish the voluntary act of a patient who is still capable of eating and drinking, making the decision to refuse food and fluids from the natural anorexia and loss of thirst that frequently accompany the end stages of dying. While some consider refusal of food and fluid to be a form of suicide, others view this as a decision to forego life-sustaining treatment. When nurses care for patients who want to refuse food and fluids, they must ensure that this is an informed and voluntary choice and remember that honoring this preference requires the support of the family, physician, and health care team who focus on palliative measures as the dying process unfolds (Quill & Byock, 2000, p. 410).

Active and Passive Euthanasia

Euthanasia literally means "good dying." **Active euthanasia** is taking specific steps to cause a patient's death, while *passive euthanasia* is defined as withdrawing medical treatment with the intention of causing the patient's death. In other words, active euthanasia is *doing something* to end a patient's life, whereas passive euthanasia is *not doing something* to preserve a patient's life. In assisted suicide (which could be considered a form of active euthanasia), the clinician provides the patient with the means to cause their own death (e.g., a prescription for a lethal dose of barbiturates). In active euthanasia, the clinician acts directly to cause the death of the patient (e.g., administers a lethal dose of medication).

Until recently, most societies maintained that the distinction between "killing" and "allowing to die" was morally relevant. This meant that passive euthanasia, the withholding or withdrawing of medically ineffective or disproportionately burdensome therapies, was morally and legally justified even when this hastened or directly caused a patient's death. On the other hand, making a lethal combination of drugs available to a patient wishing to die (assisted suicide) or administering a lethal injection or carbon monoxide, even when performed with compassionate intent at the request of a patient (active euthanasia), was deemed both immoral and illegal. Some are questioning this distinction today, and efforts are underway to legalize assisted suicide and active euthanasia in numerous countries. Another area of significant debate is whether the inclusion criteria for assisted suicide and active euthanasia should be broadened to include intractable psychological suffering.

Nurses are often the first to hear a patient's plea, "Please help me die." It is critical for nurses to reflect carefully on what they believe about assisted suicide and active euthanasia and how this influences the responses they make to patients. As of 2020, six states (Oregon, Washington, Colorado, Vermont, Hawaii, and California) and the District of Columbia have passed laws legalizing assisted suicide in certain limited circumstances. Laws and rulings in Montana and New Mexico are less clear but have allowed assisted suicide. If practicing in one of these states, be sure you

understand your state's requirements. Talk with your classmates about your responses to the following questions and the reflection questions in Box 44-4 (on page 1804).

- Should the principle of respect for autonomy be expansive enough to embrace respect for, and acquiescence to, a competent patient's request for assistance in dying?
- Does the right to privacy entail a person's right, in effect, to decide the time and manner of their own death and to gain assistance in implementing that decision?
- Is there such a thing as *rational* suicide?
- If assisted suicide and active euthanasia were to become accepted practices, would this simply represent a logical, defensible extension of the well-established moral basis for refusal of treatment and withholding or withdrawing treatment?
- Are assisted suicide and active euthanasia acts of mercy, morally grounded in the principles of benefiting and not harming patients and expressive of the virtues of compassion and beneficence?
- Is it possible to conceive of situations in which a nurse or a health care provider has a duty to help a patient die (specifically via active euthanasia or assisted suicide)?
- Is refusal to accede to a patient's request for assisted suicide or active euthanasia a form of abandonment, or are there limits to the duty to respect autonomy, right to privacy, and self-determination?
- Are calls for assisted suicide and active euthanasia emblematic of failure to provide adequate palliative care and to address the suffering of the dying?
- If medicine and nursing possess an "internal" morality, are assisted suicide and active euthanasia consistent with that morality?
- Should assisted suicide and euthanasia be limited to those with a terminal illness with 6 months or less to live, or should it also be an option for those with intractable psychological suffering?

Box 44-4 **Ethical Challenges: Thinking Critically About Aid in Dying: Personal, Professional, and Facility Responsibilities**

For many years, professional caregivers knew exactly how to respond when a patient expressed suicidal ideation. We "knew" that healthy minds didn't choose to end life and our responsibility was to prevent suicide, so we placed these people on suicide precautions. Today, many accept the concept of rational suicide as an autonomous choice; this opens the question of what our roles should be if someone chooses to end life sooner rather than later. This question is vitally important for professional caregivers, given the hospice philosophy to do nothing to hasten or postpone dying, and the ANA Code of Ethics for Nursing's (2015) statement: "The nurse should provide interventions to relieve pain and other symptoms in the dying patient consistent with palliative care practice standards and may not act with the sole intent to end life."

Questions for Reflection and Discussion

1. If a patient expresses the wish to commit suicide, what are my personal, professional, and facility obligations?
   - Should I compassionately counsel the person about choosing to live and initiate suicide precautions?
   - Must I share this information with the team—even if the patient requests that it be kept confidential?
   - Should I ask the patient to talk more about why they are feeling this way, using nondirective counseling to help the person clarify what they want to do?
   - May I counsel the person about safe, effective, legal ways to achieve this goal (i.e., should I become the patient's advocate)?
   - Should I develop and implement a care plan that honors the person's wishes?
2. Many people consider suicide to be a private decision. Is suicide ever private? What is the impact of a patient's successful suicide on family and staff?
3. How confident am I that I can distinguish a rational suicide from a mental health crisis?
4. How confident am I that I'm meeting the physical, psychological, social, and spiritual needs of patients? If unmet patient needs are prompting the request to die sooner rather than later, what are my responsibilities?
5. How can professional caregivers better respond to attempted suicide and successful suicide? What strategies will best meet the needs of families and staff?
6. Recent reports indicate that the U.S. suicide rate has been rising. What is my obligation as a nurse to prevent suicide?
7. How would I respond if my personal beliefs about suicide differ from those of a patient, or from a facility's philosophy and policies?
8. How would I feel about a patient's voluntarily stopping consumption of food and drink to cause their death? Is this suicide? Am I obligated to mention this as an option to patients wanting to die? If I recommend this, or even tacitly allow it, am I participating in a suicide?

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

9. Is there an ethical difference between attempting suicide with a gun, an overdose of liquid morphine, or cessation of eating and drinking?
0. Should facilities be more careful about limiting a patient's access (or a family member's access) to liquid morphine or other medications if the facility suspects the medications are being stockpiled to cause the patient's death? What would I do if I suspect a family member is stealing a patient's medication?
1. What about palliative sedation to unconsciousness? If someone wants to "go to sleep and never wake up," is that an option? Are policies that require that the patient be imminently dying appropriate? What about policies that exclude emotional angst or existential suffering as criteria? Since people choosing this option will die if we do not feed them, is this a "back door" to euthanasia?

The ANA Code of Ethics states that the nurse "should provide interventions to relieve pain and other symptoms in the dying patient consistent with palliative care practice standards and may not act with the sole intent to end life" (2015, p. 3). Yet nurses may be confronted by patients who seek assistance in ending their lives. Unless you think through this issue carefully, you will be unprepared to respond to the request, "Nurse, please help me die." The ANA's position statement on The Nurse's Role When a Patient Requests Medical Aid in Dying can be reviewed at: http://www.nursingworld.org/~49e869/globalassets/practiceandpolicy/nursing-excellence/ana-position-statements/social-causes-and-health-care/the-nurses-role-when-a-patient-requests-medical-aid-in-dying-web-format.pdf.

Palliative Sedation

Palliative sedation is the lowering of patient consciousness using medication for the express purpose of limiting patient awareness of suffering that is intractable and intolerable (Kirk et al., 2010). When patients who are imminently dying have pain and suffering that is unresponsive to other palliative interventions, palliative sedation to unconsciousness may be considered. Some are concerned that palliative sedation to unconsciousness offers a "back door" to euthanasia, since death is hastened for an unconscious patient who is not being artificially fed. Be sure to check your facility policies. Most restrict palliative sedation to unconsciousness to the imminently dying and exclude patients asking for such sedation for existential suffering or angst.

Death Certificate

U.S. law requires that a death certificate be prepared for each person who dies and specifies what information must be included. Death certificates are sent to local health departments, which compile many statistics from the information. The mortician assumes responsibility for handling and filing the death certificate with proper authorities. A clinician's signature is required on the certificate (check your state law to see if nurses can sign death certificates), as well as that of the pathologist, the coroner, and others in special cases. The nurse is responsible to ensure that the death certificate is signed.

Organ Donation

Patients who express a wish to donate functional organs, such as heart, corneas, liver, lungs, and kidneys, can fill out an organ donor consent card. In addition, depending on state law, a person may sign the back of their driver's license indicating approval of organ donation. The family of a deceased patient may also decide to donate the patient's functional organs. The nurse should be able to review options and provide consent forms to interested patients and their families.

Until recently, most organs were retrieved from totally brain-dead patients. New protocols for retrieving organs from non–heart-beating cadavers are raising multiple practice concerns. Comprehensive attention to optimal patient and family care at the time of withdrawal of life-sustaining therapy must remain the nurse's priority.

The scarcity of organs has resulted in legislation mandating hospitals and other health care facilities to notify transplantation programs of potential donors. Consult the United Network for Organ Sharing (UNOS; https://unos.org/), the private, nonprofit organization that manages the nation's organ transplant system under contract with the federal government, to learn more about donation and transplantation.

Think back to **Mr. Perez**, who was asking about advance directives and organ donation after his wife was found to have massive, irreversible brain damage. The nurse could incorporate knowledge of organ

donation to provide appropriate information for Mr. Perez so that he could make the most informed decision possible.

Autopsy

An autopsy is an examination of the organs and tissues of a human body after death. Consent for autopsy is legally required. The closest surviving family member or members usually have the authority to give or refuse consent. Some religious groups prohibit autopsies except for legal purposes.

It is usually the health care provider's responsibility to obtain permission for an autopsy. Sometimes the patient may grant this permission before death. The nurse can assist by explaining the reasons for an autopsy. Many relatives find comfort when they are told that the knowledge gained from an autopsy may contribute to advances in medical science as well as establish the exact cause of death.

If death is caused by accident, suicide, homicide, or illegal therapeutic practice, the coroner must be notified according to law. The coroner may decide that an autopsy is advisable and can order that one be performed, even if the patient's family has refused consent. In some cases, a death that occurs within 24 hours of admission to the hospital must be reported to the coroner.

FACTORS THAT AFFECT GRIEF AND DYING

Many factors, including age, family relationships, socioeconomic position, and cultural and religious influences, affect a person's reaction to death and expression of grief. Like the stages of grief reaction, these factors vary from person to person.

Developmental Considerations

Children do not understand death on the same level as adults do, but their sense of loss is just as great. Both terminally ill children and their siblings are likely to talk about and ask questions about death in an attempt to understand it. Terminally ill children require parental love and support as well as social interaction with other children. Death of a parent or another significant person can retard a child's development or may cause the child to regress developmentally. Children need to go through the same grief reactions as adults to accept such a loss and maintain emotional well-being.

The loss of a parent by a middle-aged adult helps to prepare the adult for the loss of a spouse or significant other and to accept their own eventual death. Older adults may lose a spouse or friends and relatives their own age. As this happens, they reminisce about life, put their lives and the purpose of living in perspective, and prepare themselves for their own inevitable death.

Family

Family roles have an important effect on a person's reactions to and expressions of grief. For example, the eldest sibling may feel a need to "be strong" and therefore may not grieve openly; a person who loses a spouse may display the same type of behavior to "protect the children."

The death of a child is a devastating experience for the family. The family needs time to accept the reality of the situation, opportunities to talk and to be listened to, and the experience of being able to express themselves behaviorally in a nonjudgmental environment. For example, the family of a terminally ill child may express feelings of guilt by wondering if they were responsible for the impending death. A sibling may suppress a guilt feeling for having wished the ill child (or a parent) dead. See Ganz (2019) for a discussion of how to improve family ICU experiences at the end of life.

Socioeconomic Factors

A bereaved family may suffer more acutely if there is no health or life insurance or pension after the death of the family provider. Such families face not only the loss of a loved one, but also an economic loss that may further disrupt family life. Older adults especially may be placed in a difficult position because the death of a spouse may result in the decrease or even elimination of a source of retirement income for the surviving spouse. This reduction in income may lead to loss of home, community, and support systems.

Cultural, Gender, and Religious Influences

Culture influences a person's expression of grief. In many families in the Western culture, grief is a private matter shared only with the family. As such, many people internalize their feelings of grief and may not express their feelings of loss to others. On the other hand, cultural background may necessitate that the patient's and family's public display be emotional and distressed, with loud weeping and moaning.

Although sex assigned at birth roles have become less differentiated in the past few decades, male and female reactions to death may differ. Although men are often expected to be stoic and not cry in public, women may be judged as "cold" if they do not grieve publicly. A widow who has a job may not be as emotionally distraught as a woman who needed her husband for financial and other support. Likewise, a widower who has not taken care of the children or the

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

house may view the future more bleakly than a man who has cooked meals and changed diapers. Some ethnic traditions may be ingrained in certain people. For example, the woman may be expected to be weak and need support, whereas the man may be expected to be emotionally supportive. This varies from culture to culture and from person to person.

Faith and religious practices play an important role in the expression of grief and may provide comfort and solace to the person experiencing loss. However, some people may blame God for their suffering and the death of their loved one and turn away from God. Many people who have put spiritual matters in the background of their lives have found death to be an impetus for a return to earlier practices of religion. The thought of death also invites many to contemplate life's big questions: Is there life after death? Is there a supreme being? And if there is a supreme being, where do I stand in relationship to that being? What is the ultimate source of meaning in my life? See Chapter 47 for a discussion of spiritual care.

Cause of Death

The grief response often depends on the cause of death. Many deaths are sudden and involve shock as well as normal grieving in the survivors. Death from disease may generate several types of responses, including the belief that death is a punishment (e.g., when AIDS was first diagnosed in homosexuals and drug users); terror and panic (e.g., when people are reminded of the devastation caused by plagues of earlier centuries); and guilt (e.g., when family and friends believe that they could have prevented the death).

Accidental death is often associated with feelings of bad luck. The guilt response can be enormous, especially when children die as the result of an accident. Death while defending a country usually is viewed by most of society as honorable and necessary. Violent deaths occur daily, especially in larger cities. Suicide accounts for a great number of violent deaths; in fact, among teenagers, it has become a major concern. It is also believed that many accidental deaths are actually suicides.

SUICIDE PREVENTION: MENTAL HEALTH FIRST AID

A 2016 New York Times article (Tavernise, 2016) reported that the U.S. suicide rate surged to a 30-year high, with increases in every age group except older adults. The rise was particularly steep for women. It was also substantial among middle-aged Americans, sending a signal of deep anguish from a group whose suicide rates had been stable or falling since the 1950s. Causative factors linked to the increase in suicides include economic recession, increased drug addiction, "gray divorce," increased social isolation, and the rise of the Internet and social media. During the pandemic, significant increases in feeling isolated and lonely increased the number of deaths by suicide in all ages.

What are our obligations to prevent suicide? It can be difficult for nurses to discern when someone is freely and knowingly choosing to end their life and when a genuine mental health crisis is operative. Mental Health First Aid USA teaches the risk factors and warning signs for mental health crises and discusses additional concerns and strategies for helping someone in both crisis and noncrisis situations. It focuses on a five-step action plan that you can remember with the acronym ALGEE:

- **A**ssess for risk of suicide or harm
- **L**isten nonjudgmentally
- **G**ive reassurance and information
- **E**ncourage appropriate professional help
- **E**ncourage self-help and other support strategies

Visit the Mental Health First Aid USA website (https://www.mentalhealthfirstaid.org) to access valuable resources for frontline caregivers. The *American Nurse Journal*https://www.nursingworld.org/practice-policy/nurse-suicide-prevention/ has a three-part series that aims to highlight the work of the ANA Building Strength Through Resilience Committee. To promote the mental health of nurses, the committee has developed web content that focuses on mental health promotion and prevention, suicide prevention, and grief. A full list of the committee's work can be found at (Melnyk et al., 2021). Also see the Challenging Topic on Nurse Suicide in Chapter 9.

NURSE AS ROLE MODEL

Holistic care of the terminally ill patient and family almost always involves some personal emotional investment. It is unrealistic and unfair to expect nurses to handle circumstances surrounding death without feelings. The best policy seems to be taking the time to explore your own feelings and to express them (see Promoting Health 44-1).

Promoting Health 44-1

GRIEVING

If a past or current loss is influencing your everyday functioning, use the assessment checklist to see how well you are responding to the losses in your life. Then develop a prescription for self-care by choosing

appropriate behaviors from the list of suggestions.

Assessment Checklist

☐ almost always ☐ sometimes ☐ almost never

☐	☐	☐	1. I can name the personal losses that are currently influencing my state of well-being.
☐	☐	☐	2. I have a plan that is in place for coping with these losses and helping me to cope.
☐	☐	☐	3. I understand the importance of grieving, and I actually set time aside for this self-care measure.
☐	☐	☐	4. I am comfortable with my feelings and am able to give them expression.
☐	☐	☐	5. There is someone who knows and accepts me well enough to allow me to share openly and honestly.
☐	☐	☐	6. I value being a supportive presence for people with life-threatening illnesses.
☐	☐	☐	7. I respond genuinely to the concerns and feelings of dying patients and their families; I am not afraid to cry with patients and to allow my feelings to show.

Self-Care Behaviors

1. Make a list of the losses that are interfering with your present state of well-being. These may include the loss of health, valued role, image or reputation, relationship, material object, job, or person.
2. Determine whether or not you are addressing these losses in a conscious fashion, and identify coping strategies that may be of help.
3. Try implementing a “tried and true” or new coping strategy.
4. Talk about one of these losses with a friend, religious leader, counselor, or therapist. Assess your comfort level in sharing your feelings openly. Ask the person you are sharing with how that person thinks you are responding.
5. Be honest about any maladaptive coping strategies you may be using, such as addictions, apathy (“Who cares?”), withdrawal and passivity, depression, and acting out. Get any help you need to replace these maladaptive coping measures.
6. Reflect on what your level of comfort in being with people who are dying reveals about your own acceptance of the fact that we will all die.

Nurse Self-Care Alert

A nurse who neglects to deal with personal feelings about life, dying, and death is in a questionable position for analyzing and considering the needs of patients facing death. A nurse’s own feelings play a major role in determining the care given to a patient with a terminal illness. Some questions nurses should use to help clarify their thinking and feelings about dying and death include:

- If I could control the events that result in my own death, where would I want to be? What cause of death would I choose? Whom would I want to have present during my terminal illness?
- What fears do I have about death?
- How would I answer these same questions for a patient for whom I have been caring?
- How could I improve the quality of care for a terminally ill patient for whom I am caring?
- If I were a member of the patient’s family, what things would I want a nurse to do for me?

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

FIGURE 44-4. A nurse grieves the loss of a patient.

Nurses who care for a patient for an extended period may undergo a grief reaction when the patient dies (Fig. 44-4). Grief after the death of a patient is natural; nurses should allow themselves to go through the grieving process rather than shut off the grief. Work pressures can make it difficult to create the time and space to respond to a patient's death, but nursing leadership is increasingly affirming the need to do this. *CriticalCareNurse* editor Annette M. Bourgault wrote a poignant editorial about the importance of nurses taking the time to grieve all the colleagues we lost to COVID-19. See the accompanying Through the Eyes of a Nurse.

Through the Eyes of a Nurse

Honoring Our Fallen Colleagues and Ourselves: Taking Time to Grieve

Sadly, at the time of writing, an estimated 7,000 or more health care workers from around the world have died from COVID-19… Of the 1,361 U.S. health care providers who died, more people of color and nurses (85) have died compared with other races and health care disciplines. The majority of media reports speak about the *number* of deaths. We hear about aggregate losses in the news but often lose sight of the individuals who lost their lives. What we have lost are people, real people who were valuable and meaningful to our critical care community. We lost a considerable amount of critical care knowledge, experience, and talent that cannot be easily replaced. We have lost trusted colleagues who had our back, who mentored us, and who shared laughs and cried with us. Not only were the deceased your colleagues, in many cases, they were your friends and, in some cases, they were family or loved ones.

You may have already honored fallen colleagues in your own way on an individual basis or with your team. Honoring those who have died through a short observance known as The Pause is a practice you may want to be familiar with. The Pause was developed by critical care nurse Jonathan Bartels for critical care nurses and their teams… It was also a way for health care providers to take a breath and reflect on their contribution rather than rushing away to another complex and busy emergency immediately following resuscitation efforts.

According to the Institute for Healthcare Improvement, grief is a near-universal aspect of disasters. Grief during the pandemic may be due to a variety of sources, such as loss of general safety; loss of autonomy; separation from family; financial loss; lack of patient visitation; social distancing; social isolation; and death of patients, colleagues, and loved ones… We each cope with death and dying in our own personal way, yet it is necessary to openly acknowledge our grief to begin dealing with pain and loss. Talking about your experiences, including end-of-life care, with friends, families, and/or colleagues has been found to help validate feelings, share grief, and provide healing support. Strategies to enhance positive coping mechanisms include self-care such as exercise, sleep, healthy diet, leisure activities, and spiritual or religious support. Although self-care during the midst of a pandemic may seem counterintuitive, it helps health care workers to cope with death and continue to provide compassionate, empathetic, and effective care.

… The year 2020 has been a year like no other. I hope you will join me as I pause to take a big breath, reflect, and honor our fallen colleagues. I will also be thinking about all of you and how much you have given of yourselves during the past year. I honor each of you… Please take good care and know you are deeply appreciated.

Annette M. Bourgault, PhD, RN, CNL, FAAN
Editor, CriticalCareNurse

Nurses should also address their personal health needs.

NURSING PROCESS FOR GRIEVING OR DYING PATIENTS AND FAMILIES

The nursing process is a helpful tool when caring for patients who are grieving or dying as well as caring for their families and significant others.

Assessing

Focused assessment for those experiencing loss, grief, and dying is directed toward determining the adequacy of the patient's and family's knowledge, perceptions, coping strategies (see Chapter 43), and resources. Pertinent interview questions are highlighted in the Focused Assessment Guide 44-1. Holistic assessment of both the dying patient and of concerned family, friends, and family/caregivers is essential to diagnosing problems.

Diagnosing Actual or Potential Health Problems and Needs

An assessment of a grieving, seriously ill, or dying patient may lead to the identification of one or more actual or potential health problems and needs. Following the formulation of the actual or potential health problems and needs, the nurse communicates findings to other nursing and health care professionals through the use of the written and spoken word. The written actual or potential health problem or need becomes a permanent part of the patient's health record.

The International Classification for Nursing Practice (ICNP) identifies several actual or potential health problems that may be identified by nurses:

- Conflicting Attitude toward Treatment
- Despair
- Difficulty Coping
- Dysfunctional Grief
- Fear about Being a Burden to Others
- Fear about Death
- Hopelessness
- Impaired Ability of Caregiver to Perform Caretaking
- Impaired Health Maintenance
- Risk for Suicide

Common etiologic factors and potential signs and symptoms for some of these health problems are found in the accompanying box, Examples of Actual or Potential Health Problems and Needs: Loss and Impending Death. Box 44-5 provides an overview of the nursing process related to the seriously ill or dying person's impaired health maintenance.

Focused Assessment Guide 43-1

EXPERIENCE OF LOSS, GRIEF, DYING, AND DEATH

Assessment Priorities

- Patient and family's understanding of medical condition, prognosis, and dying process
- Patient and family's attitude toward death and dying and knowledge of the dying process
- Patient's preferences for end-of-life treatment and care, such as desire to be at home or in a hospital, and decisions concerning treatment, resuscitation, advanced life support, organ donation, and so forth
- Documented evidence of advance care planning
- Existence of an advance directive **(It is critical that the authorized decision maker be known to all members of the health care team.)**
- Religious beliefs
- Cultural influences
- Stage of grief and death reaction
- Adequacy of coping behaviors
- Adequacy of resources
- Physiologic needs of the patient, for example, personal hygiene, pain control, nutritional and fluid needs
- Psychological needs of the patient and family, for example, fear of the unknown, pain, separation
- Spiritual needs of the patient and family: need for meaning and purpose, for love and relatedness, for forgiveness, for hope

Factors to Assess	Questions and Approaches
Adequacy of knowledge base	What have you been told about your condition? What do you know about this condition? Please describe what you have been told about your treatment options. Is there anything you don't understand about what your doctor is recommending? What else would you like to know about your present condition and treatment options? Do you know how to contact your doctor and to get the information you need or desire? *OBJECTIVE: to identify whether*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

	the patient's and family's knowledge will allow them to make informed decisions that will serve their best interests.
Realism of expectations and perceptions	Have you had any previous experiences with this condition or with the death of someone you love? What are your expectations in this case? How do you see the next few weeks (days) playing out? What are your fears, hopes, concerns, worries? What good do you think might be happening in the midst of all this? *OBJECTIVE: to discover whether the patient and family have unrealistic expectations or misperceptions about the diagnosis, prognosis, and care options that will interfere with their decision making and coping.*
Adequacy of coping strategies	Dealing with our own dying is a once-in-a-lifetime experience, and sometimes we begin the process feeling totally unprepared. Tell me something about how you think you are coping with all this. How well do you think those around you are coping? How can I help you develop or tap the resources that will help you to cope better? *OBJECTIVE: to identify whether the patient and family are using effective coping strategies. If you detect problems, try to identify coping strategies they have used effectively in the past. Also, identify and address destructive habits that have not served them well in the past such as addictions, destructive relationships, passivity, and acting out. Creatively problem solve about new strategies they might try.*
Adequacy of resources	What is helping you to get through this? Do you think the resources available to you are adequate? If the sky was the limit, what help would you wish for? What is interfering with your getting the help you need? What community resources might be of help to you? Are you using these? *OBJECTIVE: to assess the adequacy of the human, financial, spiritual, and psychological resources available to the patient. Questions should be directed to determining what, if anything, is interfering with the patient using whatever resources are available to facilitate coping.*
Signs and symptoms	A holistic assessment of the patient and the patient's family and caregivers should be performed. *OBJECTIVE: to detect problems with coping that result in fatigue, decreased energy, decreased self-care (deficient grooming, unplanned weight loss), and other maladaptive responses.*

Examples of Actual or Potential Health Problems and Needs

LOSS AND IMPENDING DEATH

Actual or Potential Health Problems and Needs	Possible Etiologic Factors	Potential Signs and Symptoms
Fear about Being a Burden **Conflicting Attitude toward Treatment**	• Patient's increasing dependence on family, especially spouse, to meet activities of daily living (hygiene, nutrition, medication administration, mobility, etc.) • History of being fiercely independent • Patient has rejected a lung transplant • Transplant team wants to list them for a second lung transplant • Family wants the patient to live.	• Talks frequently about not wanting to be a burden • Decreased requests for assistance • Expressions of sadness, "I'm not good for anything anymore…" • "I don't want to give up, I've never been a quitter, but I don't think I can go through all of this again." • "It's true that there is still so much I want to do, but maybe not in this life."
Risk for Impaired Ability of Caregiver to Perform Caregiving	• Patient's increasing dependency • Discharged home with significant needs • Increase in care needs • Caregiver's unstable health condition	—
Readiness for Enhanced Coping	—	• Verbalizes that he knows his days are few and begins to express how he wants to spend his time.

Outcome Identification and Planning

Nursing care should be directed toward the achievement of the following goals or outcomes for grieving and dying patients and their families.

The patient or family will:

- demonstrate freedom to express feelings, needs, fears, and concerns.
- identify and use effective coping strategies.
- accept the need for help as appropriate and use available resources.
- make health care decisions reflecting personal values and goals; ultimately feel peaceful about their role in decision making.
- declare and record preferences regarding treatment options.
- report sufficient relief of pain to interact meaningfully with family and to attend to everyday concerns.
- experience a dignified and comfortable death.
- resolve grief after a suitable period of mourning and resume meaningful roles and daily activities (family or significant others).

The patient and the family should take an active role in planning for care. Such planning takes the patient's preferences into consideration, facilitates the acceptance of death by the patient and the family, and provides interventions to meet holistic needs.

Implementing

In addition to promoting a comfortable, dignified death, the nurse's aims in caring for dying patients and their families include facilitating coping of the dying person and family and promoting health and preventing illness of the family. The display box titled Focus on the Older Adult (on page 1812) provides indicators for a comfortable, dignified, and peaceful death. See Jensen et al. (2020) for a discussion of practice recommendations for end-of-life care.

Developing Trusting Nurse–Patient and Nurse–Family Relationships

Communication is a lifelong need up to the moment of death and should be maintained at all times with the patient and family. To develop meaningful communication, the nurse must develop a trusting relationship with the patient. The nurse needs listening skills and the ability to recognize both verbal and nonverbal cues given by the patient and family. These skills are discussed in Chapter 8.

Be willing to discuss the patient's fears and doubts openly and to serve as a nonjudgmental listener. However, talking with dying patients is often difficult. The following observations and suggestions by P. Rancour (personal communication, 2008) are helpful:

- Often, when patients initiate conversations about dying, you may feel unprepared for their questions. They can take you by surprise and can often lead you to believe that the patient expects a crystal ball response. Remember that the purpose of all such discussions is to keep the lines of communication open with the patient. The idea is to keep the subject of dying open to discussion and to communicate to the patient that it does not make you afraid to talk about it. An open-ended statement, such as, "Tell me what concerns you the most," provides a means of encouraging communication.

Box 44-5 **Nursing Process Related to the Seriously Ill or Dying Person's Impaired Health Maintenance**

Patients and the surrogate decision makers for incompetent patients frequently feel overwhelmed when they need to make life-and-death decisions about end-of-life care.

Assessment Priorities

The objective of assessment is to identify patients and families who are at high risk for impaired health outcomes because of their difficulty making end-of-life decisions and to provide the support they need to make appropriate end-of-life care decisions that advance the patient's interests before problems develop. Potential problems when this need is overlooked include postponement of decision making, which interferes with the patient receiving optimal care; vacillation in decision making, which disturbs continuity of care for the patient; and escalation of conflict concerning decision making, which may result in a standoff between participating parties—the patient, individual family members, and health care professionals.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Detect difficulties with making decisions: fear; insufficient or erroneous information; inadequate support; conflict between religious convictions, personal moral beliefs, and choice one wants to make; and reluctance to assume responsibility for making life-and-death decision.
- Identify what is causing the decision making to be hard for the patient or family and what type of information or support could reverse this.
- Identify potential conflicts between what the patient wants and what the patient's family or caregivers believe should be done.
- Observe the patient or the patient's surrogate decision makers for physical signs of distress that reflect feeling overwhelmed by the decision that needs to be made: signs of fatigue and general exhaustion, signs of agitation and distress, and signs of growing anger and alienation.
- Read the chart carefully to identify decisions that are pending and note the lack of movement toward a decision or toward resolution of existing conflict.

Expected Outcomes

The ethically and legally valid decision maker will achieve the following:

- Describe care options (including the option of nontreatment), listing the advantages and disadvantages of each.
- Seek clarification of options, if necessary, and whatever support is needed.
- Express fears, concerns, and hopes.
- Make an informed and voluntary choice.
- Make end-of-life decisions that reflect the patient's values and goals, advancing the patient's interests.
- Make end-of-life decisions that are consistent with the aims of medicine and nursing.

Interventions

Nursing measures revolve around identifying and supporting the morally and legally valid decision maker. The following should be considered:

- Competent patients—those who can (1) understand the information needed to make the decision, (2) reason in accord with a relatively consistent set of values, and (3) communicate a preference—have the right to consent to and to refuse any and all indicated medical treatment.
- Surrogates of previously competent patients are to be guided by what is known about the patient's values and preferences. These surrogates may be designated in an advance directive, or there may be state or province law designating a hierarchy of surrogates, such as spouse, parent, adult child, sibling; the morally valid surrogate is the one who best knows the patient and the patient's preferences.
- Surrogates deciding for a never-competent patient (child or profoundly retarded adult) must be guided by a determination of what is in the patient's best interests by referring to more objective and socially shared values.

The nurse clarifies the goal of treatment (cure, stabilization of functioning, preparation for a comfortable and dignified death) and makes sure that treatment decisions are consistent with this goal. Nursing intervention may be helpful in making sure that everyone is clear about the goal of care and changes in the goal of care as the patient's condition changes.

Because some health care providers are reluctant to accept preparation for a comfortable, dignified death as an appropriate goal of medicine, some patients have received unwanted care that needlessly prolonged their dying. Conversely, decisions are being made today for financial and other reasons that deprive patients of wanted end-of-life care. The nurse serves as an advocate for the patient and the family unless what the patient or family wants violates the profession of nursing and nursing's code of ethics or the nurse's own conscience. If your beliefs and convictions do not allow you to advocate for a patient or family when what the patient wants is legal and clinically appropriate, you should immediately seek the advice of your supervisor.

Interventions include the following:

- Providing whatever information and support the patient or family needs to make an informed and voluntary decision
- Referring the patient or family to sources that can clarify problematic aspects of the decision, such as religious authority, ethicist, legal counsel
- Identifying and addressing coercive influences on decision making, being sensitive to cultural norms; for example, whereas a controlling husband may be violating his wife's freedom to make autonomous choices in one culture, in another, it is customary for the husband (or male elder in the family) to make choices for a woman

Documentation of end-of-life care preferences of competent, or previously competent, patients is

important. This includes a written record of communication, a living will, durable power of attorney for health care, and a medical advance directive. These preferences must be communicated to those who are ordering care.

- Mediating sources of conflict
- Referring patient or family to an ethics consult team or ethics committee if conflict cannot be resolved

- Some patients may be too fearful to ask health care providers questions about dying. They often approach staff whom they perceive as less intimidating or more approachable. The question often comes in the middle of the night, when there are no distractions, when anxiety or pain may keep the patient awake, and when the patient may feel most alone with psychospiritual distress. In any case, it is often on the nurse's watch when questions about dying may arise.

Focus on the Older Adult

MEASURING QUALITY OF CARE AT THE END OF LIFE

The American Geriatrics Society developed the following statement of principles about quality care at the end of life, but these indicators work well for persons of all ages:

1. *Physical and emotional symptoms.* Pain, shortness of breath, fatigue, depression, fear, anxiety, nausea, skin breakdown, and other physical and emotional problems often destroy the quality of life at its end. Symptom management is regularly deficient. Care systems should focus on these needs and ensure that people can count on a comfortable and meaningful end of their lives.
2. *Support of function and autonomy.* Even with an inevitable and progressive decline with fatal illness, much can be done to maintain personal dignity and self-respect. Achieving better functional outcomes and greater autonomy should be valued.
3. *Advance care planning.* Often, the experience of patient and family can be improved just by planning ahead for likely problems, so that decisions can reflect the patient's preferences and circumstances rather than responding to crises.
4. *Aggressive care near death—site of death, CPR, and hospitalization.* Although aggressive care is often justified, most patients would prefer to have avoided it when short-term outcome is death. High rates of medical interventions near death should prompt further examination of provider judgment and care system design.
5. *Patient and family satisfaction.* The dying patient's peace of mind and the family's perception of the patient's care and comfort are extremely important. In the long run, we can hope that the time at the end of life will be especially precious, not merely tolerable. We must measure both patient and family satisfaction with these elements: the decision-making process, the care given, the outcomes achieved, and the extent to which opportunities were provided to complete life in a meaningful way.
6. *Global quality of life.* Often a patient's assessment of overall well-being illuminates successes and shortcomings in care, which are not apparent in more specific measures. Quality of life can be good despite declining physical health, and care systems that achieve this should be valued.
7. *Family burden.* How health care is provided affects whether families have serious financial and emotional effects from the costs of care and the challenges of direct caregiving. Current and future pressures on funding health care are likely to displace more responsibility for services and payment onto families.
8. *Survival time.* With pressures on health care resources likely to increase, there is a new reason to worry that death will be accepted too readily. Purchasers and patients need to know survival times vary across plans and provider systems. In conjunction with information about symptoms, satisfaction, and the other domains listed here, such measures will allow insights into the priorities and trade-offs within each care system.
9. *Provider continuity and skill.* Only with enduring relationships with professional caregivers can patient and family develop trust, communicate effectively, and develop reliable plans. The providers must also have the relevant skills, including rehabilitation, symptom control, and psychological support. Care systems must demonstrate competent performance on continuity and provider skill.
10. *Bereavement.* Often health care stops with the patient's death, but the suffering of the family goes on. Survivors may benefit with relatively modest interventions.

Source: From American Geriatrics Society (AGS) Ethics Committee. (1995). *The Care of Dying Patients: A Position Statement from the American Geriatrics Society. 43*(5). Author; with permission from John Wiley and Sons.

- Because of the surprising nature of such questions, you may feel tempted to escape ("I've got to go take that patient's vital signs right now…") or pass the buck ("That sounds like a question for your doctor."). Be vigilant to

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

prevent such reactions, keeping in mind that avoidance would only help reduce your own anxiety and would do nothing to assist with the patient's anxiety. It is well within the scope of your professional practice as a competent nurse to provide counseling and death education, especially when the patient asks you for it or indicates an unmet need for such information and support. *When in doubt, ask a question in response*, such as "What do you feel about that?" or "What have you been told already?" This will accomplish several things. It will help you regain your composure and will give you more information about what is on the patient's mind so that your intervention can be as specific and responsive to that patient as possible.

- Do not provide false reassurance. Remember that avoiding discussions about death robs the patient of precious time to accomplish goals that produce hope (Box 44-6). People who are dying hope for many things even when they cannot hope for a cure, such as hope for freedom from pain, to be surrounded by loved ones, and for the rest of their allotted time to be spent in meaningful pursuits.

A caring nurse feels at ease in crying with the grieving person and sharing experiences with fears, loneliness, and death. This allows the griever the freedom to express their deepest concerns. Nonverbal communication is equally important. A smile, holding a hand, and eye-to-eye contact are all meaningful (Fig. 44-5). The warmth behind the gesture and the honest concern of the nurse are what count.

Box 44-6 Enabling Hope in the Terminally Ill

These guidelines are the product of an interdisciplinary team of those providing care for the terminally ill. They are presented to encourage anyone providing care for the terminally ill to consider the crucial place of hope in their caring and also their own potential to enable such hope.

What Is Hope?

Hope is the ingredient in life that enables a person both to consider a future and to actively bring that future into being. Hope originates in imagination but must become a valued and realistic possibility for that person in order to energize action. Hope has the capacity to embrace the reality of a person's suffering without escaping from it (false hope) or being suffocated by it (despair, helplessness, hopelessness).

Hope is unique to each person. During terminal illness, the future being considered will become more focused, yet hope is essential for a person to transcend despair and complete crucial life tasks.

Enabling Hope

Acknowledging Individual Uniqueness

To enable hope, the care provider must acknowledge *the uniqueness of the person* and take seriously the dreams of the terminally ill person within the changing nature of the illness. Steps that can be taken to translate hope into accomplishment must be considered. For this to happen, care providers need to do the following:

- Consider all language used, and appreciate how easily hopes can be disabled by such terms as "hopeless situation" or "nothing more can be done."
- Encounter the person's feelings at their own level; be willing to stay at that person's level and allow them to lead.
- Be willing to take the necessary time to establish rapport with the person in order that their hopes can be shared in a supportive atmosphere. Where appropriate, use physical contact to build trust.
- Realize the changing nature of both the disease and the accompanying hopes. At one point, a hope for a cure may be the necessary activating force for a person to undergo treatment; at another, the person's acceptance of impending death may give them the energy to complete crucial life tasks or endure the many losses of terminal illness.

Granting Control

A factor crucial to the nourishing of hope within a person is that of *control.* A person must be willing to take the necessary action to achieve what is hoped for. Terminal illness places many restrictions upon a person and often robs that person of a feeling of being able to control the situation, thus leading to increasing helplessness and hopelessness. To counter this, efforts must be made not only to support a person in hoping, but also to grant the person control in bringing realistic hopes into being.

To help support a person's sense of control in order to enable active hoping, care providers need to do the following:

- Provide honest and accessible information regarding the progress of the illness.
- Allow a person to express and work through many hopes in order to develop those hopes appropriate

to them in the present context.

- Allow for freedom of choice regarding treatment options to the degree possible within the setting.
- Maximize the present possibilities for achieving hopes while allowing for the changing realities of terminal illness.

Being Aware of Your Own Feelings

Hope is strengthened by those who care for and support a terminally ill person. Within the context of illness and suffering, hope may be fragile, and must be nurtured in relationships with professional caregivers, family, and friends. To enable hope, care providers must be aware of their own hope for that person.

As a care provider, you need to do the following:

- Recognize your own assumptions regarding the particular person and how those assumptions may inhibit the enabling of hope for that person.
- Be aware of how your own hope for that person may differ from the hope being expressed by that person.
- Resist judging expressed hope and be willing to explore such hope further.
- Accept the person's present suffering. Avoid giving "false hope" that minimizes the reality of the situation ("It can't be that bad," or "Don't worry, everything will be fine"); at the same time, avoid encouraging despair by focusing only upon the illness ("God can't possibly heal you now. That cancer's all through you!").

Supporting Spirituality

A component of hope is *spirituality.* Supported by faith in God, hope is the capacity of the person to transcend present suffering, to lift their perspective to future possibilities, and so to enable the person to accomplish important life tasks. This capacity to transcend is facilitated by belief in the presence of God within the changing context of terminal illness.

To enable this spiritual aspect of hope, care providers need to do the following:

- Accept the person's own spiritual journey and present level of faith (or lack of faith).
- Be open to expressed hopes that link with religious belief (e.g., "God will cure me" or "I pray that God will take me home soon").
- Allow for spiritual struggle and its resultant emotions (e.g., anger when "the cancer is back and God has failed to cure me!"). Recognize that the level of spiritual struggle during terminal illness may increase to enable the accomplishment of crucial hope for life tasks such as reconciliation and forgiveness.
- Be prepared to accept the reality of death as an aspect of hope. Accept a person who has shifted hope to how they wish to die, to life after death, to a meeting with deceased loved ones, and so on.
- Enable a person to have access to whatever means and rites of religion that will encourage their hope.

Hearing is believed to be the last sense to leave the body; many patients retain their hearing almost to the moment of death. Demonstrate kindness and thoughtfulness by speaking to a comatose patient and encouraging family

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

members to do likewise. Explain to the patient the nursing care being given and the people and sounds in the environment.

Promoting Health Literacy

In Caregivers of Terminally Ill Patients

Patient Scenario

Marlene Bough is the 47-year-old wife of a 49-year-old man who is nearing the end of his life as a result of widely metastasized thyroid cancer. Mr. Bough was initially diagnosed almost 5 years ago, but treatment is no longer able to control the growth of malignant tumors throughout his body. He has almost constant pain, is unable to walk, and has severe pulmonary and cardiovascular impairments. The doctors have told the couple that no more can be done to prolong Mr. Bough's life and that he has, at the most, less than 6 months to live. Mrs. Bough has taken a family leave from her job as a third-grade teacher so she can care for Mr. Bough at home, even though she is very concerned about being able to care for him and afraid she will cause him further pain.

Nursing Considerations: *Tips for Improving Health Literacy*

Schedule a home care planning meeting for Marlene and others who have indicated a desire to be helpful (daughter, sister-in-law, brother, colleagues at her school) and discuss how each person can help. Include times for family and friends to stay with Mr. Bough so that Marlene can have some time away from the care responsibilities. Demonstrate and have Marlene practice moving Mr. Bough in bed, providing hygiene, and administering pain medications. Discuss the responsibilities of the hospice provider and the goals of palliative care. Provide a written list of phone numbers for health care providers, including those that would be available at any time. Encourage Marlene to ask her husband, "What concerns you most?" and then to talk openly about what kind of treatment he wants for his final days. Include the following questions:

- "Where do you want to die?"
- "What kind of medical treatment do you want and do not want?"
- "What do you consider a good death?"
- "What kind of funeral service do you want?"
- "Where do you want to be buried?"

Ensure that advanced planning documents are completed. Encourage Marlene to take some time for herself, to recognize the stress of her husband's care, to welcome the help of others, and to use support people and groups after her husband's death. At that time, ask her to be prepared to ask the following three questions to herself and her health care provider:

- What is my main problem?
- What do I need to do?
- Why is it important for me to do this?

What additional measures can you take to help maintain health literacy in this woman? What other measures would be helpful for Marlene if she did not speak English, could not read, or had other learning disabilities?

Research in Nursing

Bridging the Gap to Evidence-Based Practice

Helping Patients and Families Make Decisions About End-of-Life Treatment and Care

Needing to provide ineffective and sometimes actually harmful interventions to seriously ill and dying patients in intensive care units (ICUs) troubles many nurses. Too often, no one calls for a family conference to clarify the patient's and family's understandings of the medical condition, reasonable expectations, and goals of care.

Related Research

Edward, K. L., Galletti, A., & Huynh, M. (2020). Enhancing communication with family members in the intensive care unit: A mixed methods study. *Critical Care Nurse, 40*(6), 23–32.

ICU nurses have particularly challenging and intense interactions with patients and their families, acting as confidantes, educators, advocates, cultural liaisons, and translators. According to Edward, Galletti, & Huynh (2020), family members rate their satisfaction with the ICU admission according to the quality of communication

they received, more than the level of care given to their loved one.

Brooks, L. A., Manias, E., & Nicholson, P. (2017). Communication and decision-making about end-of-life care in the intensive care unit. *American Journal of Critical Care*, *26*(4), 336–341.

This study used an interpretive, qualitative inquiry method with focus groups to explore the experiences and perspectives of nurses and physicians when initiating end-of-life care in the ICU. Five focus groups were conducted with 17 nurses and 11 physicians participating. The key aspects discussed included communication and shared decision making. Researchers concluded that multidisciplinary implementation and acceptance of end-of-life care plans in the ICU need improvement. Clear organizational processes that support the introduction of nurse and physician end-of-life care leaders are essential to optimizing outcomes for patients, family members, and clinicians.

Watson, A. C., & October, T. W. (2016). Clinical nurse participation at family conferences in the pediatric intensive care unit. *American Journal of Critical Care*, *25*(6), 489–497.

Realizing that clinical nurses attend family conferences in the ICU, but that their role during these meetings is not yet fully understood, researchers surveyed nurses and reviewed 40 audio-recorded family conferences conducted in the 44-bed pediatric ICU of an urban pediatric hospital. Most nurses surveyed thought it important to attend family conferences but identified workload as a barrier to attendance. Audio recordings revealed that bedside nurses attended 20 (50%) of 40 family conferences and spoke in 5 (25%) of the 20. Nurses verbally contributed 4% to 6% to the overall speech at the family conference.

Relevance to Nursing Practice

Clearly, nurses could be playing a larger role in helping patients and families make critical decisions about treatment and end-of-life care. Family conferences need to happen earlier, and strategies to improve the physical and verbal participation of clinical nurses are needed, especially in the context of previous research demonstrating the need for more attention in family conferences to social–emotional support and patient advocacy.

Explaining the Patient's Condition and Treatment

All involved health care personnel should know exactly what the patient and family have been told. Conflicting information puts the nurse and other team members at cross-purposes and causes the family to distrust the patient's caregivers. Because patients and families often direct questions about the patient's prognosis to the nurse, the nurse should take the initiative in ensuring that terminology, prognosis, and the description of the progress are consistently presented and explained.

Explain the patient's condition and treatment to both the patient and the family. Patience is required during explanations. The patient and family members may be so overwhelmed by the diagnosis that they do not hear all the information that is shared with them. Question them to learn how much they have retained, then repeat the information they missed. Explain care options, as well as the expected outcomes of each option, fully.

Sadly, many health care professionals do not embrace "good dying" as a legitimate aim of medical and nursing care. As a result, the dying of many patients is painfully prolonged because no one initiates a patient or family conference to clarify the treatment goals when cure is no longer an option (see Promoting Health Literacy in Caregivers of Terminally Ill Patients). The nurse plays a key role in helping the patient and family prepare for a comfortable and dignified death. Here, the primary focus is palliative, such that the patient and family accept that death is inevitable and now focus on how to spend the remaining days. For some, this means a referral to hospice or a palliative care program. Nurses play an important role in ensuring that timely prognostic information is given to patients and families so that they can decide how to spend their last days together. Some patients want to "die fighting" and will insist on intensive, life-sustaining treatment until every system fails. Others will choose not to have further treatment and will want to spend their last days in a comfortable setting (see the Research in Nursing box). See the Care Coordination Checklist (Box 44-7 on page 1816) for helpful hints on thoughtful, person-centered care at the end of life and the accompanying Thoughtful, Person-Centered Practice: Challenging Topics: Medically Assisted Dying on pages 1816–1817.

Teaching Self-Care and Promoting Self-Esteem

Encourage the patient to retain independence and make decisions as long as possible. Allow the patient to manage personal hygiene practices and self-feeding for as long as possible. After the patient is confined to bed, the creative nurse and family caregivers should attempt to find self-care activities the patient can perform. When physical abilities fail, determining when to take medication, for example, may be all the control the patient can retain.

Having familiar objects in view can help make the patient feel more comfortable and secure. Whether the patient is at home or in a health care facility, it is desirable to have the environment reflect personal preferences. This gives the patient some degree of control when health and other activities of daily living have slipped out of the patient's reach. It also supports self-esteem.

In the transition from independence to interdependence and ultimately to dependence, the patient may experience

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

depression and express frustration and grief about "being a burden." It is crucial for professional and nonprofessional caregivers to respond to the dying patient as a person of worth whose life has meaning and value. Chapter 8 discusses practical ways in which nurses can use looks, touch, words, and actions to communicate respect and caring.

Teaching Family Members to Assist in Care

Preparing family members to help provide care yields benefits to both the patient and family members. Having loved ones near comforts the patient. Family members, too, are comforted by knowing that they helped comfort the patient. Teach family members how to provide care to the patient. Family members may not want to provide physical care themselves but may want to know what to expect and how they can psychologically aid the patient. Provide assistance in this area by explaining the patient's condition, what treatment the patient is undergoing, and what result the family can expect from the treatment. Knowing the facts may help family members to cope better with impending loss.

Box 44-7 End-of-Life Care Coordination Checklist

Consider These Suggestions as You Coordinate End-of-Life Care

□ Know the patient and the person

- Include the patient and family in developing specific patient-centered goals.
- Communicate and collaborate as a health care team member.
- Provide thoughtful, person-centered care.
- Reflect as a nurse and with patient/family about plans.
- Use available resources to support the patient and family during transitions.
- Listen to the patient and family.

□ Assessment questions to ask the patient

- "What activities are you having difficulty doing now that you were able to do 3 months ago?"
- "Describe your pain and how it's different now than 3 months ago."
- "How does your pain (shortness of breath, fatigue, other symptoms) affect your activities of daily living?"
- "What work/hobbies does your illness prevent you from doing?"
- "What coping strategies do you use when stressed?"
- "What are your concerns (or fears) for the future?"

□ Exploring the patient's goals

- "If you were given a 3-month life expectancy, what would you want to accomplish?"
- "What plans have you made to do when you return home?"
- "What resources do you have to accomplish your goals?"
- "What resources will you need to accomplish your goals?"
- "Who have you included to be with you as a part of your goals?"

□ Developing patient-centered goals

- "It sounds like you want (fill in with restatement of patient's goals)."
- "What resources are available to help you meet your goal?"
- "What, if any, changes will your family need to consider to help you meet your goal?"
- "How will you accomplish your goal?"
- "What modifications might be needed (such as home, job, family obligations, cultural influences, spiritual considerations) to meet your goal?"

□ Involving the family

- "What help will you need when (call the patient by name) is discharged?"
- "How do you cope with stress (anxiety, change)?"
- "What's your understanding regarding the plan of care?"
- "What concerns (or fears) do you have?"

Thoughtful, Person-Centered Practice: Challenging Topics

Medically Assisted Dying

Many controversial issues make it challenging to know how to respond as a professional nurse in select scenarios. Often, the nurse's personal and/or professional values may conflict with options desired by patients, families, employers, and communities. Not infrequently, nurses must make clinical judgments balancing, promoting, and safeguarding personal integrity and respecting the values and preferences of patient. The *Essentials* competencies for nurses includes 9.5b, Demonstrate the core values of professional nursing identity, 9.5c, Demonstrate sensitivity to the values of others, and 9.5d, Demonstrate ethical comportment and moral courage in decision making and actions (American Association of Colleges of Nursing [AACN], 2021).

Read the scenario below and see if you can articulate what you believe, why you believe this, and how these beliefs are likely to inform the decisions you make and your behavior, especially when you are confronted with competing obligations. Based on Tanner's Clinical Judgment Model (2006), consider reflection-in-action and reflection-on-action (Nielson et al., 2007).

Reflection-in-Action

As you read, consider what the student is thinking at the moment—what happened? How did the patient, family, and/or health care provider respond? What did the nurse do next?

Scenario

Mr. Sam Wallner was diagnosed with extensive stage small cell lung cancer and was told that the cancer had spread too far for surgery or radiation therapy to be useful as the initial treatment. Since until this time he had been in fairly good health, chemotherapy, possibly with an immunotherapy drug was suggested in hopes of shrinking the cancer, treating symptoms, and helping to live longer. The nursing student was shocked when Mr. Wallner asked their opinion about the likelihood that the chemotherapy and immunotherapy would have any benefit. "I've heard horror stories about all sorts of cancer treatments, and I don't want to start something that will just make me feel more miserable. Maybe it's time to pack it in?" Since this happened on the first day of their rotation in the oncology unit, they could not answer the question about the likely benefits of the proposed treatment, but promised to get an answer for Mr. Wallner. The nurse left the room wondering if Mr. Wallner had been serious about "packing it in," and what exactly was meant by this.

Effective Noticing (Cues)

1. What did you notice about the situation initially? What information/observations are significant? What information deviates from what is expected/normal/usual?

Effective Interpreting

2. How would you prioritize this data? What other assessment data, evidence, and/or information would you need to consider the situation? How would you obtain this additional information?
3. What do you think about this situation? Consider personal and previous nursing experiences that you have had and formal knowledge (physiology, psychology, communication skills) that may be of assistance in providing care in this situation.

Scenario

The student was able to find the oncology nurse practitioner, and she shared Mr. Wallner's questions. The nurse practitioner promised to accompany the student back to his room to answer his questions about the probable benefits of treatment, but he asked the student what she thought Mr. Wallner meant about "packing it in." The student replied, "He seems pretty scared, and I thought he was asking me if dying sooner rather than later was a good option." She shared with the nurse practitioner, "I don't believe I'd feel comfortable talking with him about that option—I'm not sure what I believe. I was raised as a Christian, and suicide was never an approved option." Medically assisted dying legislation was recently passed in this state, and the student knew that its legalization was a heated topic. She had never been asked by a patient to help them die before and she wasn't sure how she should respond. "You'll talk to the patient about this, too, right? I need to do more research before I understand my professional responsibilities."

Now, consider the nurses' decisions and reflect on your learning. See if you can articulate what you believe, why you believe this, and how these beliefs are likely to inform the decisions you make and your behavior, especially when you are confronted with competing obligations.

Effective Responding

4. How would you describe the obligations the student has in this scenario to her patient, to herself, and

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

to her team?

5. If you cannot fulfill each of these obligations, how will you prioritize them? What basis/rationale do you use for prioritization? Remember that the ANA *Code of Ethics for Nurses* reminds us that "the nurse's primary commitment is to the patient," while, at the same time, states that "the nurse owes the same duties to self as to others, including the responsibility to promote health and safety, preserve wholeness of character and integrity, maintain competence, and continue personal and professional growth."

Effective Reflecting

When the student talks with her faculty, her preceptor, other nurses on the unit, and other students, she is not surprised to learn that there are many opinions about what a competent and compassionate response to the patient's questions should look like. These range from being a cheerleader for aggressive treatment to being an advocate for his right to use the new legislation to obtain the means to end his life when he is ready. Several nurses have already read the legislation and are ready to coach patients on how to meet the criteria, and to "accompany them" on this stage of their life journey. Because the legislation is so new, the hospital has yet to draft a policy on how to respond to a request for medically assisted dying, should this be what the patient wants. The student also realizes that there are many palliative care options to explore before the patient chooses medically assisted dying. Given her unfamiliarity with this topic, the student is happy to defer to the experience of the nurse practitioner and promises to continue to educate herself. She is eager to observe the nurse practitioner's conversation with Mr. Wallner. She realizes in a more poignant way, the importance of what she says to patients and the power her words may have in life-and-death decisions.

6. Do you agree with the choice the student made? Would you have made the same choice, why or why not? What would inform your decision?
7. Do you agree with the criteria the nurse used to evaluate her decision? How do you evaluate your clinical and moral judgments?
8. What resources can you access to better inform your decision?
9. Whether or not you decide to try and respond to Mr. Wallner, how might you use reflective practice to evaluate your decision so you can respond more confidently in the future? What criteria will you use to evaluate a good response?
10. What personal attributes and competencies are most likely to lead to a good response?

Reflection-on-Action

Then look back at the student's decisions and reflect on your learning—how did your knowledge and/or skills expand based on this scenario? What attitude, value, or belief shifts did you experience (if any) after reading this scenario? What would you do differently if you were in this situation? What more do you need to know to be able to manage this or a similar situation in the future?

Nielson, A., Stragnell, S., & Jester, P. (2007). Guide for reflection using the clinical judgment model. *Journal of Nursing Education*, *46*(11), 513–516.

Olsen, D. P., Chan, R., & Lehto, R. (2017). Ethical nursing care when the terminally ill patient seeks death. *American Journal of Nursing*, *117*(7), 50–55

Tanner, C. A. (2006). Thinking like a nurse: A research-based model of clinical judgment in nursing. *Journal of Nursing Education*, *45*(6), 204–211.

Meeting the Needs of the Dying Patient

There are many ways you can intervene to meet the needs of the dying patient. Many hospice professionals use the nonpharmacologic side to guide family education. Please refer to online Student Resources for this text for a helpful four-page nonpharmacologic/pharmacologic symptom management guide (used with permission, Hospice of the Valley, Phoenix, AZ).

ADDRESSING PHYSIOLOGIC NEEDS

Physiologic care of the patient involves meeting physical needs such as personal hygiene, pain control, nutritional and fluid needs, movement, elimination, and respiratory care. Personal hygiene includes cleanliness of the skin, hair, mouth, nose, and eyes. Frequent baths and linen changes may be necessary. The mouth and nose should be kept free of mucus, and secretions should be wiped from the eyes.

The health care provider determines the medication and dosage needed for pain control, but the patient's wishes should be considered (see Chapter 36 for further discussion of pain control). Some patients prefer and are able to control their own medication. A patient requiring nutritional support should be encouraged to take sips of water or ice chips if still able to swallow. The dying patient may elect to forego artificial nutrition and hydration because the burdens of feeding and hydrating artificially may outweigh the benefits. Problems with elimination include the

development of incontinence, constipation, and urinary retention. Absorbent pads or a nearby bedpan or urinal may be used for patients experiencing incontinence; laxatives or enemas may be used for relieving constipation; and catheterization may be required for urinary retention. Bed linens should be changed often. Periodic movement should also be assisted; regular changes of position help prevent pressure injuries. Repositioning the conscious patient in semi-Fowler's position can facilitate respirations; positioning the unconscious patient in a semiprone position allows drainage of saliva and mucus. Oxygen therapy may be necessary for some patients.

ADDRESSING PSYCHOLOGICAL NEEDS

When people speak of their fears of death, responses typically include fear of the unknown, pain, separation, leaving loved ones, loss of dignity, loss of control, and unfinished business. Kübler-Ross believes that there is still another, more overwhelming and more significant fear that often is repressed and unconscious: that of the catastrophic, destructive force that has befallen a person and that the person cannot change. Kübler-Ross points out that terminally ill people communicate this fear of a destructive force but do so largely through symbolic language. A person may use nonverbal language, such as a facial expression, a particular kind of handclasp, or, in the case of children, drawings and manner of play with toys. Verbal communication may also be used symbolically.

A fear of isolation, of having to face death alone, is a primary concern of the dying patient. Support the patient by indicating your presence, giving full attention, and showing that you care. Encourage the presence of family members in the room and sharing of reminiscences. There is now a national volunteer program designed to provide companionship and support for dying persons so that no patient dies alone (http://www.eskenazihealth.edu/programs/noda). Check to see if your hospital has a "No one dies alone" program.

ADDRESSING NEEDS FOR INTIMACY

Terminally ill patients and their sexual partners may feel uncomfortable discussing their needs for intimacy. Partners may wish to be physically intimate with the dying person but are afraid of "hurting" them and may also be afraid that an open expression of sexuality is somehow "inappropriate" when someone is dying. Encourage discussion and suggest ways to be physically intimate that will meet the needs of both partners. A loving foot massage or a tender, cradling body embrace may be exactly what a dying person needs in their last moments.

ADDRESSING SPIRITUAL NEEDS

Although not all patients follow specific spiritual or religious beliefs, most require some form of spiritual care. Many terminally ill patients find great comfort in the support they receive from their religious faith. Help obtain the services of clergy or pastoral care workers as the situation indicates. Most patients need to feel that their lives have meaning; many feel a need for hope in the face of death. Spiritual needs are discussed more fully in Chapter 47.

Meeting the Needs of the Family

The nurse can provide care for the family facing loss by listening to their concerns. Family members need to verbalize their worries and fears; nurses and other health care personnel can provide support by being nonjudgmental listeners. Likewise, nursing care of the grieving family involves communication and listening. Use the communication skills discussed in Chapter 8 and earlier in this section to be a nonjudgmental listener. Feedback to the family can be provided by summarizing or paraphrasing, without questioning the validity of the family's emotions. Be sure that all family members, including children, are able to participate in the grieving process. Family members may need to be reminded to get rest and to eat. Too many visitors may tire the patient; when explanations are offered, most relatives readily understand this.

The reality of death can be made less painful by preparing the family ahead of time. When the process has been explained to the family, they are better prepared to understand the needs of the dying person and how to support the person.

Explain the steps of the grieving process to all family members ahead of time so that they will recognize the specific stages as they experience them and understand that the process is normal. They can then recognize that other members of the family are going through the same stages, perhaps at different times. This preparation promotes better understanding and communication within the family.

Death creates a change in family roles. As one person (the dying person) leaves a role, adjustments must be made within the family to compensate. Each member plays a part in that compensation, and the nurse can help with these adjustments.

Providing Postmortem Care

When a patient dies, the nurse's responsibilities include caring for the patient's body, caring for the family, and discharging specific legal responsibilities. The last involves ensuring that a death certificate is issued and signed, labeling the body, and reviewing organ donation arrangements, if any.

CARING FOR THE BODY

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

After the patient has been pronounced dead, the nurse is responsible for preparing the body. The body is placed in normal anatomic position to avoid pooling of blood, soiled dressings are replaced, and tubes are removed. In most cases, it is unnecessary to wash the body; the mortician normally attends to this. Some religions strictly forbid washing of the body, whereas in others a special person must perform it. In cultures in which the family's washing of the deceased's body is considered the last service a family can give a loved one, the family should be given the necessary supplies and left alone in the room with the body. If an autopsy is to be performed, any tubes that were in place should not be removed. In such cases, the nurse should follow the facility's policy.

Through the Eyes of a Student

We had had several day-shift clinical rotations, but this was our first evening clinical experience. We were unsure as to what the evening would be like. We knew the evening would provide us with a new outlook on nursing, but we were not prepared for what unfolded.

I had been taking care of a patient when another nursing student asked if I would check in on her patient while she had her dinner break. Each of the students knew this patient because we all had the pleasure of caring for him. I was told he was lying in bed watching television and that he had changed his code status to "DNR" (do not resuscitate) just that day. When I went to check on him, I found him lying in bed but not watching television. His eyes were closed as if he were sleeping peacefully. His mouth was open, and his respirations were slow. I spoke his name several times without a response. At the same time, I was also checking for a radial pulse. When I couldn't find his pulse, I swiftly walked to find the instructor. Together we went back to him and assessed his condition. There were no radial or carotid pulses. His chest was now not rising, and the instructor listened to his heart with a stethoscope. There wasn't a heartbeat. I stood there feeling helpless and low spirited. This was a man to whom we had all grown close. His family came to see him and to say a few final words. Tears were shed not only by his family but also by those of us who had cared for him.

Our first evening clinical was an extremely emotional night. We were all quiet as we walked down the hallway to go home. The student who was caring for him that night was stopped by his daughter and two young granddaughters. One granddaughter was wearing his hat and the other was carrying his belt. This man's daughter was brokenhearted by his death yet needed to know that he wasn't alone when he died. The student told her that I had been the one with him. The daughter seemed relieved to know that he was not by himself when he died.

As I look back on that evening, I'm sad that this man is no longer with us. I did not know him for very long, but he touched me in a way that helped me understand the true meaning of nursing: not only to care for the sick, disabled, or enfeebled, but also to be human and offer support for grieving families.

—Joyce A. Shearman, Delaware County Community College, Media, Pennsylvania

The nurse is legally responsible for placing identification tags on either the shroud or garment the body is clothed in and on the ankle to ensure that the body can be identified even if it is separated from its shroud. The nurse also places an identification tag on the patient's dentures or other prostheses to ensure that the mortician receives these. The importance of proper and complete identification cannot be overemphasized. The patient's body may be placed in the hospital's morgue refrigerator if mortuary arrangements were not made before the patient's death. If the patient died of a communicable disease, the body may require special handling to prevent the spread of disease. Requirements for such handling are usually specified by local laws and depend on the disease-causing organism, mode of transmission, and other characteristics.

CARING FOR THE FAMILY

After a patient has died, the nurse provides support and care to the patient's family (see Through the Eyes of a Student). In most cases, this involves listening to the family's expressions of grief, loss, and helplessness. Because comforting words are often difficult to find, offer solace and support by being an attentive listener. Family members may need to see the patient's body to accept the death fully; in such cases, arrange for family members to view the body before it is discharged to the mortician.

Sudden death creates unique problems for the family. In the case of sudden injury or illness, the physical needs of the patient are paramount to the health care team. This means that family members are not provided as much emotional support or information as they would be if the patient's illness were prolonged, nor are they permitted to exercise as many options regarding the patient's care. The family that loses a member unexpectedly has not had an opportunity to begin the grieving process or to share in grieving with the deceased person. Allow family members to express grief and provide emotional support. Often the family is in the emergency department waiting room when death is confirmed. They are stunned, bewildered, and numb. Do not rush them from the waiting room, but rather provide them with a private place to begin their grieving. Acknowledge their shock and listen to their grief. The family needs guidance in making plans and help in making decisions.

It is appropriate for the nurse who was caregiver or who took care of the patient for a prolonged period to attend the funeral. It also is appropriate for the nurse to make a follow-up call to the patient's family after the funeral or memorial service to offer both concern and care for the family's well-being. Follow-up visits are important to give support to the family. If the nurse assesses that the family is not coping well, appropriate referrals should be made. If the patient was cared for by a hospice, the family is offered grief support for up to a year following the death.

CARING FOR OTHER PATIENTS

Because nurses in institutional settings often provide care to more than one patient at a time, after the death of one patient, the nurse must continue to provide care to the other patients. Other patients are often aware of a death and may need to be consoled; this is particularly true of a patient who has shared a room with the deceased patient. Other patients may have grief reactions and should be supported through the grief process. Death of a patient may cause depression in other patients and may make them more aware of their own future deaths.

CARING FOR ONESELF

Witnessing the deaths of patients we have cared for can take a toll on health care professionals who can become numb or burned out. Nurses are now being encouraged to "pause" after a patient dies to silently reflect and honor the life. It is also a good time to be grateful for the care that you provided the patient. "Pause" guidelines are now being implemented in many settings that stop professional caregivers in a reflective moment of silence to honor the newly dead (Mason & Warnke, 2017).

Evaluating

The nursing care plan for dying patients is effective if patients meet the outcome of a comfortable, dignified death and family members resolve their grief after a suitable time of mourning and resume meaningful life roles and activities. See the Evolving Case Study 44-1 for Mrs. Esposita and Her Family.

REFLECTIVE PRACTICE LEADING TO PERSONAL LEARNING

Remember that the object of reflective practice is to look at an experience, understand it, and learn from it. As you begin to develop your expertise in identifying and responding to needs related to loss, grief, and dying, reflect on your experiences—successes and failures—in order to improve your practice. I don't think any nurse forgets the first time they cared for a patient who died. It can be scary and make us feel uncomfortable.

- What are your experiences with the seriously ill and dying and their families?
- Have you encountered patients or their family caregivers whose holistic needs are unmet?
- If you identified such a need, did you feel confident and comfortable responding to these needs?
- Have your care plans ever identified and addressed needs specifically related to loss, grief, and dying?
- Are you familiar with the palliative care resources available in your practice settings?
- Have you tried to learn more about these members of the interprofessional team and how you can develop collaborative relationships that will best serve your patients?
- Have you ever consulted with a palliative care or hospice professional?

Remember, we create the memories families will live with for the rest of their lives.

EVOLVING CASE STUDY 44-1

Scenario: The Espositas have been married for 19 years and have two children, Jorge, who is 16, and Marita, who is 13. It has been 2 years since Mrs. Esposita was diagnosed with ovarian cancer, and this period has been difficult for the entire family. At present, she is extremely cachexic (thin) and in the end stage of her illness. She initially tried aggressive treatment, and several chemotherapy regimens failed. During her last hospitalization 2 months ago, a decision was made not to continue cancer treatments and to transition to purely palliative goals, and Mrs. Esposita told her family she wanted to die at home.

QUESTION r/t CUES: Which assessment data is of highest priority for the nurse to collect to provide additional information to address the family's ability to care for Mrs. Esposita at home?

A. The family's knowledge about ovarian cancer and appropriate therapies.
B. The condition of Mrs. Esposita's skin.
C. Mrs. Esposita's mental health and well-being.
D. The adequacy of the husband's and children's coping strategies.
E. The availability of community resources.

Scenario: Until now, Mrs. Esposita wanted nothing to do with the local hospice because of a reported "bad experience" a neighbor had. Her insurance will not provide for all the home nursing care she needs, and her

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

husband and children have been trying to meet her needs for nursing as well as run the house and meet their own needs. A demanding woman, Mrs. Esposita never seems satisfied with anything anyone does, and the family is looking utterly frustrated, angry, and fatigued. Her son Jorge is coping by "opting out"; he frequently spends the night with friends and doesn't even call home to report on his whereabouts. Daughter Marita's grades have fallen, and she has dropped out of cheerleading and other school activities so that she can take care of her mother.

QUESTION r/t ANALYZING CUES: What other information (assessment data or evidence) should the nurse obtain related to this issue? Select all that apply.

A. Did Mrs. Esposita have a case manager or social worker who explored and recommended community resources?
B. Medication record.
C. Degree to which Mrs. Esposita understands the effect she is having on the well-being of her family.
D. Family's willingness to sacrifice their interests to care for their mother.

Scenario: Mr. Esposita, who has been silent until now, recently confided that he doesn't know how much longer he can go on this way, and seemed horrified to hear himself say, "I just wish she would die already and get this all over with!" He is very concerned about the changes in his children and feels powerless to change what is happening.

QUESTION r/t PRIORITIZING HYPOTHESIS: Based on the assessments of this patient, which priority problem should the nurse identify to guide the plan of care?

A. Conflicting Caregiver Attitude
B. Impaired Family Coping
C. Death Anxiety
D. Despair
E. Helplessness

Scenario: The nurse decides to focus on each member of the family's coping strategies and to explore the possibility of there being untapped community resources to supplement their reserves.

QUESTION r/t GENERATING SOLUTIONS: Which intervention will be most effective to help each member of the family develop healthier coping strategies? Select all that apply.

A. Reassure Mr. Esposita and the children that their mother's death is imminent and that they will be able to return to their usual lives in good time.
B. Compliment Marita for the sacrifices she is making and suggest at some level her mother must understand and be grateful.
C. Help Mr. Esposita develop clearer guidelines for Jorge and effective punishments.
D. Communicate clearly that many families facing similar struggles find it difficult to be patient with themselves and with one another. Normalize their responses.
E. Encourage each family member to identify helpful and nonhelpful coping behaviors and to devise positive coping strategies.

Scenario: Marita tells the nurse that her mother seems much sleepier now. "When I come home from school, I can hardly wake her. It also seems like her liquid morphine is disappearing quickly. You don't think dad might be overdosing her, do you?"

QUESTION r/t TAKING ACTION: The nurse confirms what Marita is telling her and realizes that a response is indicated. What is the priority nursing intervention?

A. Assess if the changes in Mrs. Esposita are the result of her worsening condition as death nears and if she has been receiving more morphine in response to worsening pain.
B. Call 911 and ask for an ambulance.
C. Call the police and report your suspicions.
D. Confront Mr. Esposita with Marita's concerns and ask for an explanation of what is happening.
E. Allow the family dynamics to play out.

QUESTION r/t EVALUATING OUTCOMES: The nurse visits the family upon learning that Mrs. Esposita died and makes a follow-up bereavement call 6 months after her death. Which of the following parameters indicates a successful implementation of the plan of care? Select all that apply.

A. Mr. Esposita thanks you for your assistance during a hard time for everyone.
B. Marita's grades have started to improve, and she is eager to go back to cheerleading next year.
C. Mr. Esposita thanks you for being patient with all of them. "I can't believe I wanted this all to be over, but I guess I'm glad she's in a better place now. Have to admit I miss her a lot."
D. Jorge is still that absent family member who says he is too angry to spend time at home and pretend that everything is OK.

E. Mr. Esposita shyly asks you if you'd like to come over for dinner some Sunday evening.

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

. Work through the Thoughtful, Person-Centered Practice: Challenging Topics: Medically Assisted Dying 44-1 and Evolving Case Study 44-1, Mrs. Esposita and Her Family, to help develop your clinical reasoning and clinical judgment skills.
. Recall personal losses (death of a family member or friend; loss of a significant relationship, job, or opportunity) and recollect what you were experiencing at the time. Try to remember what your expectations were for those to whom you looked for support and how your ability to cope was influenced by whether those expectations were met. Remembering that no two people respond to loss in exactly the same way, develop a list of nursing measures to help patients who are dealing with loss. Compare your list with other students' lists and incorporate their ideas.
. Compare and contrast the care a patient dying of cancer would receive in a critical care unit with the care they would receive at home with hospice care. Identify the advantages and disadvantages of each. Talk with family members and friends about their preferences. Use your analysis to help describe these options to prospective patients.
. Role-play a situation with a peer in which you counsel a woman with cancer who is told that cure is no longer an option and that she has less than 6 months to live. What will you say to elicit the patient's preferences for treatment and care? Reflect on how your experiences, beliefs, and values might affect what you say to patients and how you say it.
. You have to call the family of a patient who died alone in a nursing home. What do you say? Would you matter-of-factly report, "I am sorry to tell you that your mother died this evening," or would you use terms like "passed" or "is no longer suffering"?
. How would you respond if the woman described in Item 4 above asks you to "Please help me die"? What knowledge, skills, and attitudes do you need to respond well to this question?
. You meet a couple who has never "gotten over" the death of their 22-year-old daughter. The 2022 edition of the *Diagnostic and Statistical Manual of Mental Disorders*, Fifth Edition, includes a controversial new diagnosis: prolonged grief disorder. Many have argued to see intense grief as a target for medical treatment. Its inclusion in the DSM-5 means that clinicians can now bill insurance companies for treating people for the condition. Opponents warn that the designation risks pathologizing a fundamental aspect of the human experience. Some people actually emerging slowly but naturally from their losses may be told by their doctors that they have mental illnesses. What are the potential benefits and harms of adding intense grief to the manual of mental disorders? What resources can you tap to answer this question? Do you believe it would be helpful for this couple to have prolonged grief disorder medical diagnosis? (Barry, E. March 18, 2022. How long should it take to grieve? Psychiatry has come up with an answer. *The New York Times* https://www.nytimes.com/2022/03/18/health/prolonged-grief-disorder.html. .)

PRACTICING FOR NCLEX

. A nurse midwife is assisting a patient whose birth plan states she is firmly committed to natural childbirth. When informed the infant is in distress and a cesarean delivery is necessary, the pregnant patient sobs inconsolably, calling herself a failure. The nurse offers emotional support based on what likely types of losses? Select all that apply.

a. Actual
b. Perceived
c. Psychological
d. Anticipatory
e. Physical
f. Maturational

. A hospice nurse who cared for a dying patient and their family documents that the family is experiencing a period of mourning. Which behaviors would the nurse expect to see at this stage? Select all that apply.

a. The family arranges for a funeral for their loved one.
b. The family arranges for a memorial scholarship for their loved one.
c. The coroner pronounces the patient's death.
d. The family arranges for hospice for their loved one.
e. The patient is diagnosed with terminal cancer.
f. The patient's daughter writes a poem expressing her sorrow.

. An older adult who recently moved into a long-term care facility tells the nurse their only son died 20 years ago, and they haven't enjoyed life since. When giving report to the next shift, the nurse tells the oncoming nurse the resident seems to be suffering from which type of grief?

a. Somatic

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

b. Anticipatory
c. Unresolved
d. Inhibited

. A home health care nurse has been caring for a patient with advanced AIDS who is working through the stages of death and dying. The nurse documents the patient has entered the acceptance phase of death when the patient makes which statement?

a. "I've made peace with everyone, and I'm actually ready to move on."
b. "God cannot possibly be good if He allows people to get this horrible disease."
c. "I just want to get better. A friend of mine had success with a plant-based diet."
d. "The test results must be mixed up with someone else's; I feel better now."

. A patient tells the nurse it is unfair that they should have to die now when they have finally made peace with their family. Which response by the nurse would be most appropriate?

a. "I'm sorry you're feeling this way when death is inevitable."
b. "It does seem unfair. Tell me more about how you are feeling."
c. "You'll come to acceptance soon; no one knows how much time they have."
d. "Tell me about your pain. Did it keep you awake last night?"

. A nurse is caring for a terminally ill patient who says, "I just can't sleep. I keep worrying about what my family will do when I am gone." What response by the nurse is most appropriate?

a. "You need your sleep for your visitors tomorrow."
b. "What seems to be concerning you the most?"
c. "Your family told me they will be fine."
d. "I suggest you discuss this with your family."

. A patient tells a nurse that their daughter has been appointed to make decisions for them should they become incapacitated. What follow-up question would the nurse ask?

a. "Did the health care provider complete a Physician Order for Life-Sustaining Treatment (POLST) form?"
b. "Do we have a copy of your durable power of attorney for health care?"
c. "Have you prepared a living will?"
d. "Should I phone your provider for you to sign an Allow Natural Death (AND) form?"

. A group of nursing students in a leadership course are studying the ANA position regarding assisted suicide. The professor asks the students for the best response to a note written by a ventilator-dependent patient "help me end my suffering, I don't want to live anymore." Which nursing response is consistent with the ANA's position?

a. "I will do everything possible to keep you comfortable but will not administer medication to cause your death."
b. "Being removed from the ventilator is a form of active euthanasia, which is not supported by the nurses' code of ethics."
c. After exhausting every intervention to keep a dying patient comfortable, the nurse says, "Let's talk about when and how you want to die."
d. "I'm personally opposed to assisted suicide, but I'll find you a colleague who can help you."

. A patient with end-stage breast cancer has been in the medical intensive care unit for 3 weeks. Her husband tells the nurse that his wife was very clear about not wanting aggressive treatment that would merely prolong her dying. Which type of order could the nurse suggest the husband discuss with his wife's health care provider?

a. Comfort Measures Only
b. Do Not Hospitalize
c. Living Will
d. Slow Code Only

. A nurse in the intensive care unit is preparing a patient's family for terminal weaning from mechanical ventilation. What nursing actions would facilitate this process? Select all that apply.

a. Offering the family information about the advantages and disadvantages of continued ventilatory support
b. Explaining to the family what will happen at each phase of the weaning and offer support
c. Validating orders for sedation and analgesia to promote comfort and dignity
d. Explaining that death occurs quickly after the patient is removed from the ventilator
e. Teaching the family that the decision for terminal weaning must be made by the primary care provider
f. Arranging mandatory counseling for the patient and family to assist them in making this end-of-life decision

. The parents of an infant in the neonatal intensive care unit (ICU) for several months also have a 22-month-old child at home. The nurse notes the parents seem chronically fatigued, express guilt about neglecting their child at home, have

been short tempered, and express anxiety about their continued ability to manage their family. The nurse plans to address which of these health problems in the plan of care?

a. Dysfunctional Grief
b. Fear about Being a Burden to Others
c. Impaired Ability of Caregiver to Perform Caretaking
d. Impaired Health Maintenance

. A nurse is caring for terminally ill patients in a long-term care setting. Which nursing action is appropriate during end-of-life care?

a. Avoiding disturbing a comatose patient by speaking to them while providing care
b. Holding the hand of a dying patient and crying with the patient and family
c. Requesting a social work consult for family members with multiple complaints about the care
d. Performing hygiene for the patient because it is easier than having the patient help

. After validating an autopsy is not planned, a new graduate nurse provides postmortem care. Which action requires the preceptor to correct the graduate?

a. Leaving the patient in a sitting position at the family's request
b. Placing identification tags on both the shroud and the ankle
c. Removing soiled dressings and tubes, while washing the body
d. Ensuring a death certificate is issued and signed

. The family of a patient who has just died asks for privacy and supplies to wash their loved one's body. How does the nurse best respond?

a. Inform the family that there is no need for them to wash the body since the funeral home typically does this.
b. Explain that hospital policy forbids their being alone with the deceased patient.
c. Provide the requested the supplies and maintain a watchful eye to ensure they maintain the patient's dignity.
d. Provide the requested supplies, assess if this request is linked to religious or cultural customs, and offer assistance.

. An older adult who has had multiple strokes is refusing artificial nutrition and hydration against medical advice and in opposition to their daughter. The patient's nurse advocates for the patient, stating which party is the most appropriate decision maker?
Electronic Health Record (EHR), Consultations Tab Psychiatric Consult: Patient is competent, understands the consequences of her actions, no depression noted. Patient persists in refusing treatment. Suggest ethics consultation.

a. Patient
b. Patient's daughter
c. Health care provider
d. Ethics consult team

. A nurse receives information in a shift report that a patient who has rapidly progressing terminal illness is in the denial phase of death and dying. The nurse expects a patient in this stage to make which statement?

a. "I can't wait to get out of the hospital and plan next year's beach vacation."
b. "I've chosen my favorite music and readings for my memorial service."
c. "The people in this hospital are so incompetent, what a bunch of idiots!"
d. "I cry every time I wonder how my children will get along when I'm gone."

. A nurse notes a hospice patient is increasingly agitated, with noisy, irregular breathing and periods of apnea. The skin of their feet appears mottled. The nurse takes which action?

a. Activates the rapid response team to treat shock
b. Contacts the respiratory therapist for a nebulizer treatment
c. Prepares the patient's family for imminent death
d. Inserts an oropharyngeal airway for suctioning

ANSWERS WITH RATIONALES

. **a, b, c.** The losses experienced by the pregnant patient are actual, perceived, and psychological. Actual loss can be recognized by others as well as by the person sustaining the loss; perceived loss is experienced by the person but is intangible to others; and psychological loss is a loss that is felt emotionally as opposed to physically. Anticipatory loss occurs when one grieves prior to the actual loss; physical loss is tangible and perceived by others; and maturational loss is experienced as a result of natural developmental processes.

. **a, b, f.** Mourning refers to the actions and expressions of grief, including the symbols and ceremonies (e.g., a funeral or final celebration of life) that make up the outward expressions of grief. It is a period of grief and acceptance, as the person learns to deal with their loss. A diagnosis of cancer and the coroner's pronouncing the patient's death are not

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

behaviors of the family during a period of mourning. Arranging for hospice care precedes a patient's death.

. **c.** Dysfunctional grief is abnormal or distorted; it may be either unresolved or inhibited. In unresolved grief, a person may have trouble expressing feelings of loss or may deny them; it may also describe a state of bereavement that extends over a lengthy period. With inhibited grief, a person suppresses feelings of grief and may instead manifest somatic (body) symptoms, such as abdominal pain or heart palpitations. Anticipatory loss or grief occurs when a person displays loss and grief behaviors for a loss that has yet to take place.

. **a.** According to Kübler-Ross, when the patient reaches the stage of acceptance, they feel tranquil. This patient has accepted the reality of death and is prepared for the transition to death.

. **b.** This response by the nurse validates the patient's feelings, saying they have been heard, and invites them to share more of their feelings, concerns, and fears. The other responses either deny the patient's feelings or change the subject.

. **b.** Using an open-ended question, such as, "What seems to be concerning you the most?" encourages communication. False reassurances or side-stepping the statement are not helpful. The nurse then would assess the patient's restlessness and consider possible comfort measures.

. **b.** A durable power of attorney for health care appoints an agent the person trusts to make decisions in the event of subsequent incapacity. Living wills provide specific instructions about the kinds of health care that should be provided or foregone in particular situations. A POLST form is a medical order indicating a patient's wishes regarding treatments commonly used in a medical crisis. The living will is a document whose purpose is to allow people to record specific instructions about the type of health care they would like to receive in particular end-of-life situations. AND on the medical record of a patient indicates the patient or surrogate has expressed a wish that there be no attempts to resuscitate the patient.

. **a.** The ANA Code of Ethics states that the nurse "should provide interventions to relieve pain and other symptoms in the dying patient consistent with palliative care practice standards and may not act with the sole intent to end life" (2015, p. 3). Removing mechanical ventilation or other life support at the patient's request or request of the surrogate when treatment is futile is not performed with the sole intent to end life but to promote dignity and comfort. Nurses should be prepared to respond to the request: "Nurse, please help me die…."

. **a.** The nurse could suggest that the husband speak to the health care provider about a Comfort Measures Only order in which the goal of treatment is a comfortable, dignified death, and further life-sustaining measures have been declined. A Do-Not-Hospitalize order is often used for patients in long-term care and other residential settings who refuse hospitalization for further aggressive treatment. A living will is a document in which the patient provides specific instructions about the kinds of health care that should be provided or foregone in particular situations in which they are unlikely to recover. A Slow Code refers to a delay in calling a code and beginning resuscitation efforts until these measures will be ineffective. This is not consistent with current best practice and may be forbidden in certain facilities. A nurse could be charged with negligence in the event of a Slow Code and resulting patient death.

. **a, b, c.** A nurse's role in terminal weaning is to assist patients and families in the decision-making process by offering helpful information about the benefits and burdens of continued ventilation. The nurse teaches what to expect if terminal weaning is initiated, including the use of sedation and analgesia for patient comfort. Supporting the patient and family and managing sedation and analgesia are critical nursing responsibilities. In some cases, competent patients decide that they want to discontinue their ventilatory support; more often, the surrogate decision makers determine that continued ventilatory support is futile. The nurse would not predict the time until death. Once removed from the ventilator, a patient may not resume spontaneous breathing or may breathe on their own, living for hours, days, or rarely, longer. Counseling may be arranged if requested but is not mandatory for decision making.

. **c.** Impaired ability of a caregiver to perform caretaking applies to these parents. Even with a positive outcome, the infant in the ICU is likely to be discharged with many needs, which may still impact them and their other child. Grief is an expression of loss, but the focus here is on the parents' exhaustion and coping. The health problem of being a burden refers to a patient's fear, rather than the caregiver. There is no specific information about the health maintenance needs of the child, rather, in this situation, the parents are the focus of care.

. **b.** The nurse should not be afraid to show compassion and empathy for the dying person, including crying with the patient or family. The sense of hearing is believed to be the last sense to leave the body before death; therefore, the nurse should explain care to comatose or unresponsive patients. The nurse should address caregiver role endurance by actively listening to family members. Encouraging the dying patient to remain active and participate in care for as long as possible is appropriate, rather than taking over self-care measures.

. **a.** Because the body should be placed in normal anatomic position to avoid pooling of blood, leaving the body in a sitting position is contraindicated. The other actions are appropriate nursing responsibilities related to postmortem care.

. **d.** The family may want to wash the body for personal, religious, or cultural reasons and should be allowed to do so. This action may reflect caring, the last service to a loved one, or promote acceptance of death.

. **a.** Because this patient is competent, they have the right to refuse treatment felt to be disproportionately burdensome, even if this hastens their death. Neither her daughter nor her doctor has authority to assume decision-making

responsibilities unless appointed as surrogates. The ethics consult team is not a decision-making body; they can make recommendations but have no prescription authority.

. **a.** In the denial phase, the patient denies the reality of death and may repress what is discussed. The patient may think, "They made a mistake in the diagnosis" or "they mixed up my records with someone else's." Planning a vacation for the following year indicates the patient is not ready to take in the information. When the stage of acceptance is reached, the patient feels tranquil and has accepted the reality of and is prepared for death. The patient may think, "I've tied up all the loose ends." In the anger phase, the patient expresses rage and hostility and may adopt a "why me?" attitude. During the depression phase, the patient goes through a period of grief before death. The grief is often characterized by crying and not speaking much.

. **c.** Signs of imminent death include difficulty talking or swallowing; urinary or bowel incontinence or constipation; loss of movement, sensation, and reflexes; decreasing body temperature with cold or clammy skin; weak, slow, or irregular pulse and decreasing blood pressure; noisy, irregular, or Cheyne–Stokes respirations; restlessness or agitation and/or; cooling, mottling, and cyanosis of the extremities and dependent areas. The purpose of hospice care is to provide comfort as death approaches rather than invasive interventions. As death approaches, the irregular noisy breathing is expected; nebulizer treatments are not the priority.

Sensory Functioning

Ori Soltes

Ori, a 28-year-old man, is in the intensive care unit (ICU) after a motor vehicle crash that resulted in multiple internal injuries as well as fractures. He is being monitored continuously and receiving mechanical ventilation. On the fifth day after the crash, he begins to exhibit transient episodes of acute confusion.

Muriel Hao

Muriel is a 56-year-old woman who had surgery 2 days ago. She denies any complaints of pain or discomfort. She is receiving intravenous (IV) therapy via an infusion pump. She states, “Please stop that beeping. It’s driving me nuts and I can’t rest.”

Dolores Pirolla

Dolores, a 74-year-old woman, comes to the older adult clinic with her 77-year-old husband who was diagnosed with macular degeneration and progressive vision loss. She states, “Now I’ve noticed he’s also having difficulty hearing me. I’m worried because he doesn’t want to leave the house and we hardly see any of our friends anymore. We used to go out to the movies or dinner at least once a week. Lately,

if we get out once a month, that's a lot!"

Learning Outcomes

After completing the chapter, you will be able to accomplish the following:

. Describe the four conditions that must be met in each sensory experience.
. Explain the role of the reticular activating system in sensory experience.
. Identify etiologies and perceptual, cognitive, and emotional responses to sensory deprivation and sensory overload.
. Perform a comprehensive assessment of sensory functioning using appropriate interview questions and physical assessment skills.
. Develop actual and potential health problem statements that correctly identify sensory/perceptual alterations that may be treated by nurses.
. Describe specific nursing interventions to prevent sensory alterations, stimulate the senses, promote health literacy, and assist patients with sensory difficulties.
. Develop, implement, and evaluate a plan of nursing care to help patients safely meet individualized sensory/perceptual outcomes.

Nursing Concepts

Sensory perception

Key Terms

adaptation
arousal
auditory
disturbed sensory perceptions
gustatory
kinesthesia
olfactory
proprioception
reticular activating system (RAS)
sensoristasis
sensory deficit
sensory deprivation
sensory overload
sensory perception
sensory poverty
sensory processing disorder
sensory reception
stereognosis
stimulus
tactile
visceral
visual

A person's senses are vital to survival, growth and development, and the experience of bodily pleasure and pain. Nurses encounter many patients who have impaired sensory functioning that places them at risk for injury, disturbed growth and development, and decreased well-being. Moreover, the stress of illness or trauma and the need for diagnosis and treatment may quickly result in sensory deprivation or overload, with serious disturbances in visual, perceptual, cognitive, or emotional functioning (see the Reflective Practice box for an example). Nurses are in the position to use

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

knowledge of sensory functioning to support positive outcomes for patients (see Box 45-1). For example, awareness of the intensities and sources of sound, ways to control noise, and the assessment of patients' perceptions of and responses to sound can provide nurses with a basis for therapeutic manipulation of the environment.

SENSORY EXPERIENCE

Reception and Perception

The sensory experience consists of two components: reception and perception.

Sensory reception is the process of receiving data about the external or internal environment through the senses. The senses by which people maintain contact with the external environment are vision, hearing, smell, taste, and touch. The terms used to describe the senses are **visual** (pertaining to sight), **auditory** (pertaining to hearing), **olfactory** (pertaining to smell), **gustatory** (pertaining to taste), and **tactile** (pertaining to touch). In addition, **stereognosis** is the sense that perceives the solidity of objects and their size, shape, and texture. See Figure 45-1 on page 1830.

People orient themselves internally by the kinesthetic and visceral senses. **Kinesthesia** refers to awareness of positioning of body parts and body movement; **visceral** pertains to inner organs. The kinesthetic and visceral senses arise internally from muscles and hollow organs, respectively, and are the body's basic orienting systems. **Proprioception** is the term used to describe the sense, usually at a subconscious level, of the movements and position of the body and especially its limbs, independent of vision. This sense is gained primarily from input from sensory nerve terminals in muscles and tendons and the fibrous capsules of joints combined with input from the vestibular apparatus.

Sensory perception is the conscious process of selecting, organizing, and interpreting data from the senses into meaningful information. Perception is influenced by the intensity, size, change, or representation of stimuli, as well as by past experiences, knowledge, and attitudes.

For a person to receive the necessary data to experience the world, four conditions must be met:

Box 45-1 Healthy People 2030 Goal

Overview

Many people in the United States will have a sensory or communication disorder in their lifetime. This includes problems with vision, hearing, balance, smell, taste, voice, speech, or language. Healthy People 2030 focuses on preventing, diagnosing, and treating these disorders in people of all ages.

Sensory or communication disorders can have a major impact on social, emotional, and physical well-being. Some groups have a higher risk of these disorders, including people with low incomes, people who work in certain industries, and older adults. People who are diagnosed or treated later often have worse outcomes.

Preventive care such as hearing screenings for newborns and comprehensive eye exams in adults are critical for finding and treating these disorders early. Strategies to increase use of eye and hearing protection can help prevent new cases.

See the Healthy People 2030 website for specific objectives: https://health.gov/healthypeople/objectives-and-data/browse-objectives/sensory-or-communication-disorders

Source: Reprinted from HealthyPeople.gov. (n.d.). *Healthy People 2030: Hearing and other sensory or communication disorders*. Retrieved January 15, 2022, from https://health.gov/healthypeople/objectives-and-data/browse-objectives/sensory-or-communication-disorders

QSEN Reflective Practice: Cultivating QSEN Competencies

CHALLENGE TO TECHNICAL SKILLS

All throughout nursing school, we are taught theory, and from that theory we are to use clinical reasoning and clinical judgment to determine how to care for a particular patient, focusing on the patient, not the machines surrounding them. "You'll learn that later," they say.

I was assigned to care for Muriel Hao, a 56-year-old woman who had surgery 2 days ago. As I walk into her room, I check to see if she is comfortable and whether she needs anything at that particular point in time. She asks me one favor. "Please stop that beeping. It's driving me nuts and I can't rest." So, I look at the machine, dumbfounded, and worried that the patient is going to think I am incompetent because I cannot even work a simple machine. No theory from a classroom is going to teach me how to make the machine stop beeping. To make things worse, every facility has different machines. As nursing students, we go from one facility to another, trying to get accustomed to the equipment and technologies of each one. I assume that things will get easier once I have steady employment in a facility. If that particular facility changes its technologies, I would hope that there would be an in-service on the new technology.

But what do I do now, as a nursing student?

Thinking Outside the Box: Possible Courses of Action

- Press the buttons on the machine, and hope that the beeping goes away.
- Seek out someone who does know how to work the machine and have that person fix it so I don't do more damage.
- Find someone who knows how to work the machine, have that person fix it, and then have the person explain to me how to fix it so I can do it next time.

Evaluating a Good Outcome: How Do I Define Success?

- Personal integrity is maintained (if I can't fix it, I feel stupid, and that's an insult to my integrity).
- Professional integrity remains intact (if I can't fix it, I will feel incompetent as a nurse—if I can't even fix a machine, how am I supposed to help a person?).
- The patient expresses relief that the beeping has stopped, and she is now able to rest.

Personal Learning: Here's to the Future!

Although this does not seem like a huge or very troublesome problem, every nursing student can probably attest to feeling this way at least once. The first few times it happened to me, I just asked someone to fix it for me, thinking it was a one-time problem. Then I realized that this is something that I was facing over and over again. So, I asked someone to show me how to fix the problem if it should occur again. I understood what to do and knew how to do it. Then we switched hospitals and I was confused once again. In today's environment of ever-changing technology, I realized that it is not just the students who feel this way. Nurses, too, have these same feelings. We all learn new things every day, whether it's from a patient, another nurse, a doctor, or a technical specialist. We just need to know that it's okay to ask questions. Moreover, not knowing how to work with a piece of equipment does not mean that you are incompetent with people. Learning in the health care field is an ongoing process.

Michele Jordan, Georgetown University

QSEN SELF-REFLECTION ON QUALITY AND SAFETY COMPETENCIES DEVELOPING KNOWLEDGE, SKILLS, AND ATTITUDES FOR CONTINUOUS IMPROVEMENT

Do you agree with the criteria that the nursing student used to evaluate a successful outcome? Why or why not? What *knowledge, skills,* and *attitudes* do you need to develop to continuously improve the quality and safety of care for patients like Ms. Hao? Was professional integrity affirmed? Explain.

Patient-Centered Care: How can you deliver thoughtful, person-centered care for patients while feeling overwhelmed by their equipment?

Teamwork and Collaboration/Quality Improvement: Who on your team is most likely to help you? What communication and interpersonal skills do you need to improve to ensure that you function as a competent and confident member of the patient care team? What does quality care for Ms. Hao "look like"?

Safety/Evidence-Based Practice: What does the evidence point to as "best practice" for Ms. Hao? If you stop the machine from beeping in response to her requests, will you be silencing critical alarms? What safety needs does she have and how can you meet them?

Informatics: Can you identify the essential information that must be available in Ms. Hao's electronic record to support safe patient care and coordination of care? Can you think of other ways to respond to or approach the situation? What else might the nursing student have done to ensure a successful outcome?

FIGURE 45-1. People delight in their abilities to see, touch, smell, hear, and taste. (*Source*: Used with permission from *Shutterstock. Photos by Krakenimages.com, pixelheadphoto digitalskillet, Roman Samborskyi, LightField Studios, and ViDI Studio*.)

. A **stimulus**—an agent, act, or other influence capable of initiating a response by the nervous system—must be present.
. A receptor or sense organ must receive the stimulus and convert it to a nerve impulse.
. The nerve impulse must be conducted along a nervous pathway from the receptor or sense organ to the brain.
. A particular area in the brain must receive and translate the impulse into a sensation.

Think back to **Muriel Hao**, the 56-year-old woman unable to rest because of the machine's beeping. The nurse would incorporate knowledge of sensory reception and perception to determine that the patient is experiencing a continuous and large amount of auditory stimuli from the beeping of the machine. In addition, the nurse would need to keep in mind other sources of stimuli, such as possible visual stimuli from the lighted numbers on the machine, tactile stimuli from being touched to determine the possible problem associated with the machine, and internal stimuli associated with pain and discomfort from surgery.

Arousal Mechanism

To receive stimuli and respond appropriately, the brain must be alert or aroused. The **reticular activating system (RAS)**, a poorly defined network that extends from the hypothalamus to the medulla, mediates **arousal**. The optimal arousal state of the RAS is a general drive state called **sensoristasis**. Nerve impulses from all the sensory tracts reach the RAS, which then selectively allows certain impulses to reach the cerebral cortex and be perceived. The mesencephalic portion of the RAS appears to be the center of the system. Stimulation of this area produces the most pronounced and long-lasting effects on the cerebral cortex (Fig. 45-2). With its many ascending and descending connections to other areas of the brain, the RAS serves to monitor and to regulate incoming sensory stimuli, thus maintaining, enhancing, or inhibiting cortical arousal. States of arousal or awareness are described in Box 45-2.

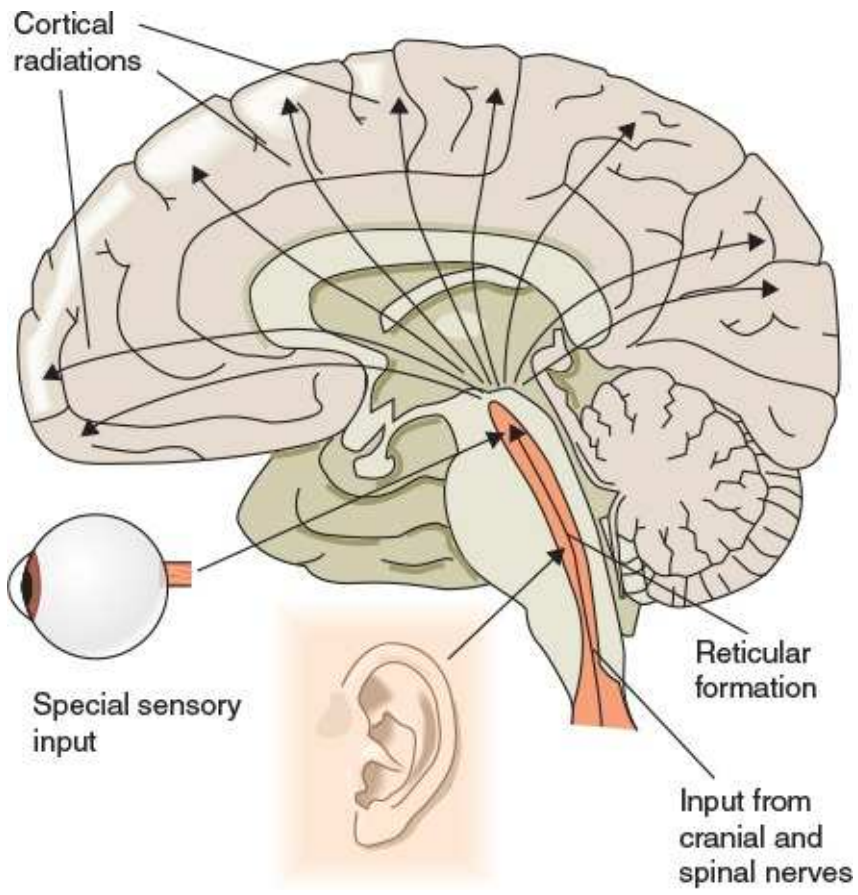

FIGURE 45-2. Nerve impulses from all the sensory tracts reach the reticular activating system (RAS), which then selectively allows certain impulses to reach the cerebral cortex and to be perceived.

Box 45-2 **States of Arousal/Awareness**

Conscious States

Delirium: Disorientation, restlessness, confusion, hallucinations, agitation, alternating with other conscious states

Dementia: Difficulties with spatial orientation, memory, language; changes in personality

Confusion: Reduced awareness, easily distracted, easily startled by sensory stimuli, alternates between drowsiness and excitability; resembles minor form of delirium state

Normal consciousness: Aware of self and external environment, well oriented, responsive

Somnolence: Extreme drowsiness, but will respond normally to stimuli

Minimally conscious states: Part consciousness; sleep–wake cycles present; some motor function, including automatic movements; inconsistently follows commands

Locked-in syndrome: Full consciousness; sleep–wake cycles present; quadriplegic, auditory and visual function preserved; emotion preserved

Unconscious States

Asleep: Can be aroused by normal stimuli (light touch, sound, and the like)

Stupor: Can be aroused by extreme and/or repeated stimuli

Coma: Cannot be aroused and does not respond to stimuli (coma states can be further subdivided according to the effect on reflex responses to stimuli; see Glasgow Coma Scale, Chapter 27)

Vegetative state: Cannot be aroused. Sleep–wake cycles, postures or withdraws to noxious stimuli, occasional nonpurposeful movement, random smiling or grimacing.

See the Glasgow coma scale and full outline of unresponsiveness (four) coma scale in Chapter 27.

The body quickly adapts to constant stimuli. For example, the repeated stimulus of a continuing noise, such as city traffic, or a noxious odor eventually goes unnoticed. This phenomenon is termed **adaptation**. Therefore, a stimulus must be variable or irregular to evoke a response. Impulses that are not acted on when received may be used at a later date in response to the same or similar stimuli. The memory process involves the storage of that material. For example, thought and memory are used when a new sensory experience occurs, and the person uses a response based on previous knowledge and experience. For example, if a toddler remembers a painful visit to a pediatrician, that memory can trigger avoidance behaviors with future visits.

DISTURBED SENSORY PERCEPTION

When patients are admitted to a health facility, they are confronted with stimuli that are different in quality and quantity from those to which they are accustomed. For example, a patient confined to bed rest may receive many fewer stimuli, whereas someone undergoing multiple diagnostic tests may receive a greater-than-normal level of sensory input. These

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

and other typical experiences are likely to result in **disturbed sensory perceptions** experienced by the patient. Being sensitive to how visual stimuli, noises, and touch are stimulating to the patient, combined with paying attention to the patient's need for privacy and for social interaction, can significantly reduce disturbances in sensory perception.

Severe sensory alterations can occur, especially in certain areas of a facility, such as the critical care or intensive care units; this type of sensory alteration is sometimes termed *intensive care unit (ICU) psychosis*. Factors contributing to severe sensory alteration include sensory overload, sensory deprivation, sleep deprivation, and cultural care deprivation.

Consider **Ori Soltes**, the young man in the ICU. The nurse would need to assess Mr. Soltes closely for underlying reasons for his confusion. Although the possible causes are numerous and most likely multiple in nature, the nurse would need to address the possibility of sensory deprivation and overload contributing to the patient's confusion.

Box 45-3 (on pages 1832–1833) provides an overview of sensory deprivation and sensory overload with related nursing interventions.

Sensory Deprivation

Sensory deprivation occurs when a person experiences decreased sensory input or input that is monotonous, unpatterned, or meaningless. With decreased sensory input, the RAS is no longer able to project a normal level of activation to the brain. As a result, the person may hallucinate simply to maintain an optimal level of arousal. During the COVID-19 pandemic, many people who sheltered in place experienced sensory deprivation, especially those in nursing homes who were confined to their rooms. Patients at high risk for sensory deprivation include:

- Patients in an environment with decreased or monotonous stimuli (such as institutionalized patients, or those confined to a small living area at home, on bed rest, or in isolation)
- Patients with impaired ability to receive environmental stimuli (e.g., patients with impaired vision or hearing; with bandages or casts that interfere with vision, hearing, or tactile stimulation; or with affective disorders who "close out" the environment)
- Patients who are unable to process environmental stimuli (e.g., patients with spinal cord injuries or brain damage, those who are confused or disoriented, and those who are taking prescribed or recreational drugs affecting the central nervous system)

Box 45-3 Overview of Sensory Deprivation and Sensory Overload

Sensory Deprivation

Sensory deprivation is insufficient quantity or quality of stimuli; may result from decreased sensory input or monotonous, unpatterned, and unmeaningful input.

Signs and Symptoms	Contributing Factors	Patients at Risk
Physical behaviors: drowsiness, excessive yawning *Escape behaviors:* eating, exercising, sleeping, running away to escape the deprived environment *Changes in perception:* unusual body sensations; preoccupation with somatic complaints (dry mouth, palpitations, difficulty	*Decreased environmental stimuli:* institutionalized environment; separation from significant others and usual sources of stimuli; treatments that decrease access to stimuli, such as bed rest or isolation *Impaired ability to receive environmental stimuli:* impaired vision, hearing, taste, smell, touch resulting from treatments such as bandages or body casts that	Institutionalized patients, especially those in long-term care settings Patients with communicable diseases (e.g., COVID-19, AIDS) Patients confined to bed Patients with sensory alterations (e.g., impaired vision or hearing, or patients with eye patches or body casts) Patients who are depressed Patients from a different culture Patients with a disturbance of the

breathing, nausea); change in body image; illusions and hallucinations *Changes in cognitive behavior:* decreased attention span, inability to concentrate, decreased problem solving and task performance *Changes in affective behavior:* crying, increased irritability and annoyance over small matters, confusion, panic, depression	interfere with reception of stimuli, or as a result of depression and other affective disorders *Inability to process environmental stimuli:* spinal cord injuries, brain damage, confusion, dementia, medications that depress the central nervous system	nervous system

Nursing Interventions

Maintain sufficient level of arousal by increasing sensory stimuli from all sensory modalities:

- Instruct the patient in self-stimulation methods: counting, singing, reading, reciting poetry.
- Structure meaningful tangible stimuli into the patient's external environment; include a variety of people, ideas, sensations; a pet may provide excellent stimulation.

Visual Stimulation

- Colorful sheets, pajamas, robes
- Colorful uniform tops for the nurse
- Face-to-face human contact
- Clocks, calendars, wristwatches
- Pictures, flowers, greeting cards

Auditory Stimulation

- Calling the person by name
- Conversation that communicates caring as well as orients the patient
- Reading to the patient
- Television, radio, iPod

Gustatory and Olfactory Stimulation

- Attention to oral hygiene and properly fitting dentures
- Food of different textures, colors, temperatures, served attractively
- Smelling food before eating it and recalling pleasurable aromas from the past
- Seasoning foods or having favorite foods brought from home

Tactile Stimulation

- Back rubs and foot soaks
- Turning and repositioning
- Passive range-of-motion exercises
- Hair brushing, combing, washing
- Hugs
- Touching arms or shoulders

Cognitive Input

- Orient the patient to the environment.
- Encourage patient participation in self-care.
- Discuss current events or the patient's occupation, hobbies, or interests.
- Reinforce reality without arguing with a patient who is hallucinating. "No, I don't see a man standing there, but the linen hamper may be confusing you."

Emotional Input

- Encourage the patient to share fears, concerns, and perceptions.
- Reassure the patient that illusions and misperceptions do occur with sensory deprivation.
- Incorporate culturally assistive, supportive, facilitative acts into nursing care.
- *Caution:* Because it can be difficult to distinguish the behavioral manifestations of sensory deprivation from sensory overload, introduce more stimulation cautiously. If the added stimulation only increases the patient's maladaptive behaviors, consider reducing sensory input because the patient may be

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

experiencing sensory overload.

Sensory Overload

Sensory overload is excessive stimuli over which a person feels little control; the brain is unable to meaningfully respond to or ignore stimuli.

Signs and Symptoms	Contributing Factors	Patients at Risk
Similar to those observed in sensory deprivation Older patients and patients who have suffered a stroke are more likely to experience confusion or agitation. Young patients are more likely to seek the comfort of their parents' embrace to block out sensory overload.	*Increased internal stimuli:* pain, pressure and discomfort of intrusive tubes (e.g., intravenous [IV] lines, catheters; endotracheal tubes; nasogastric tubes), worry about state of health or need to make treatment decisions *Increased external stimuli:* unfamiliar health care environment, such as lights, noises, sounds, odors, movement, and constant presence of strangers, many of whom touch the body; intrusive procedures such as diagnostic tests and treatments; scratchy linens *Inability to perceptually disregard or selectively ignore some stimuli:* nervous system disturbances, substances such as caffeine that stimulate the central nervous system arousal mechanism	Acutely or chronically ill patients Patients in pain Patients with intrusive monitoring or treatment equipment Hospitalized patients, especially those in critical care settings Patients with disturbances of the nervous system

Nursing Interventions

- Provide a consistent, predictable pattern of stimulation to help the patient develop a sense of control over the environment.
- Offer simple explanations before procedures, tests, and examinations.
- Establish a schedule with the patient for routine care such as eating, bathing, turning, positioning, coughing, and exercising.
- Speak calmly with the patient and move slowly; communicate confidence.
- Explore with the patient what stimuli are most distressing and develop a plan to reduce or eliminate them (e.g., incoming phone calls, visitors); earplugs or pain medication may be indicated. Noise-reducing headphones may be helpful.
- Be careful not to cause sensory deprivation.
- Identify and, wherever possible, eliminate culturally inappropriate stimuli.

Remember **Dolores Pirolla**, the wife of the older man with vision deficits who was developing hearing deficits. The nurse would incorporate knowledge of risk factors for sensory deprivation when developing the patient's care plan. In this case, Mr. Pirolla's sensory deficits involving vision and now hearing are affecting his ability to receive environmental stimuli. Thus, the nurse would develop a care plan with measures to ensure that the patient and his wife receive adequate stimulation from the environment.

Sensory deprivation can lead to perceptual, cognitive, and emotional disturbances. *Perceptual responses* result from inaccurate perception of sights, sounds, tastes, smells, and body position, coordination, and equilibrium. These responses can range from mild distortions such as daydreams, to gross distortions such as hallucinations. *Cognitive responses* involve the patient's inability to control the direction of thought content. Typically, attention span and ability to concentrate are decreased. The patient may demonstrate difficulty with memory, problem solving, and task performance. *Emotional responses* typically are manifested by apathy, anxiety, fear, anger, belligerence, panic, or depression. Rapid mood changes may also occur (see Box 45-2 on page 1831 for additional information).

Sensory Overload

Sensory overload occurs when a person experiences so much sensory stimuli that the brain is unable to either respond meaningfully or ignore the stimuli. The person feels out of control and may exhibit all of the manifestations observed in sensory deprivation. The amount and quality of stimuli necessary to produce overload may differ greatly from one person to another and is influenced by factors such as age, culture, personality, and lifestyle.

In some patients, especially those coming from a quiet environment with unvarying stimuli, the experience of being hospitalized quickly results in sensory overload (Fig. 45-3 on page 1834). In such patients, the brain is assaulted by the constant presence of strangers who not only demand to be spoken to, but also touch and poke at the body; by the strange sights, odors, sounds, and feels of the unfamiliar environment; by the constant presence of pain or discomfort from dressings, IV lines, drainage tubes, or endotracheal tubes; and by the ever-present worries about the meaning and course of the illness. Nursing care focuses on reducing distressing stimuli and helping the patient to gain control over the environment (see Box 45-3 on pages 1832–1833).

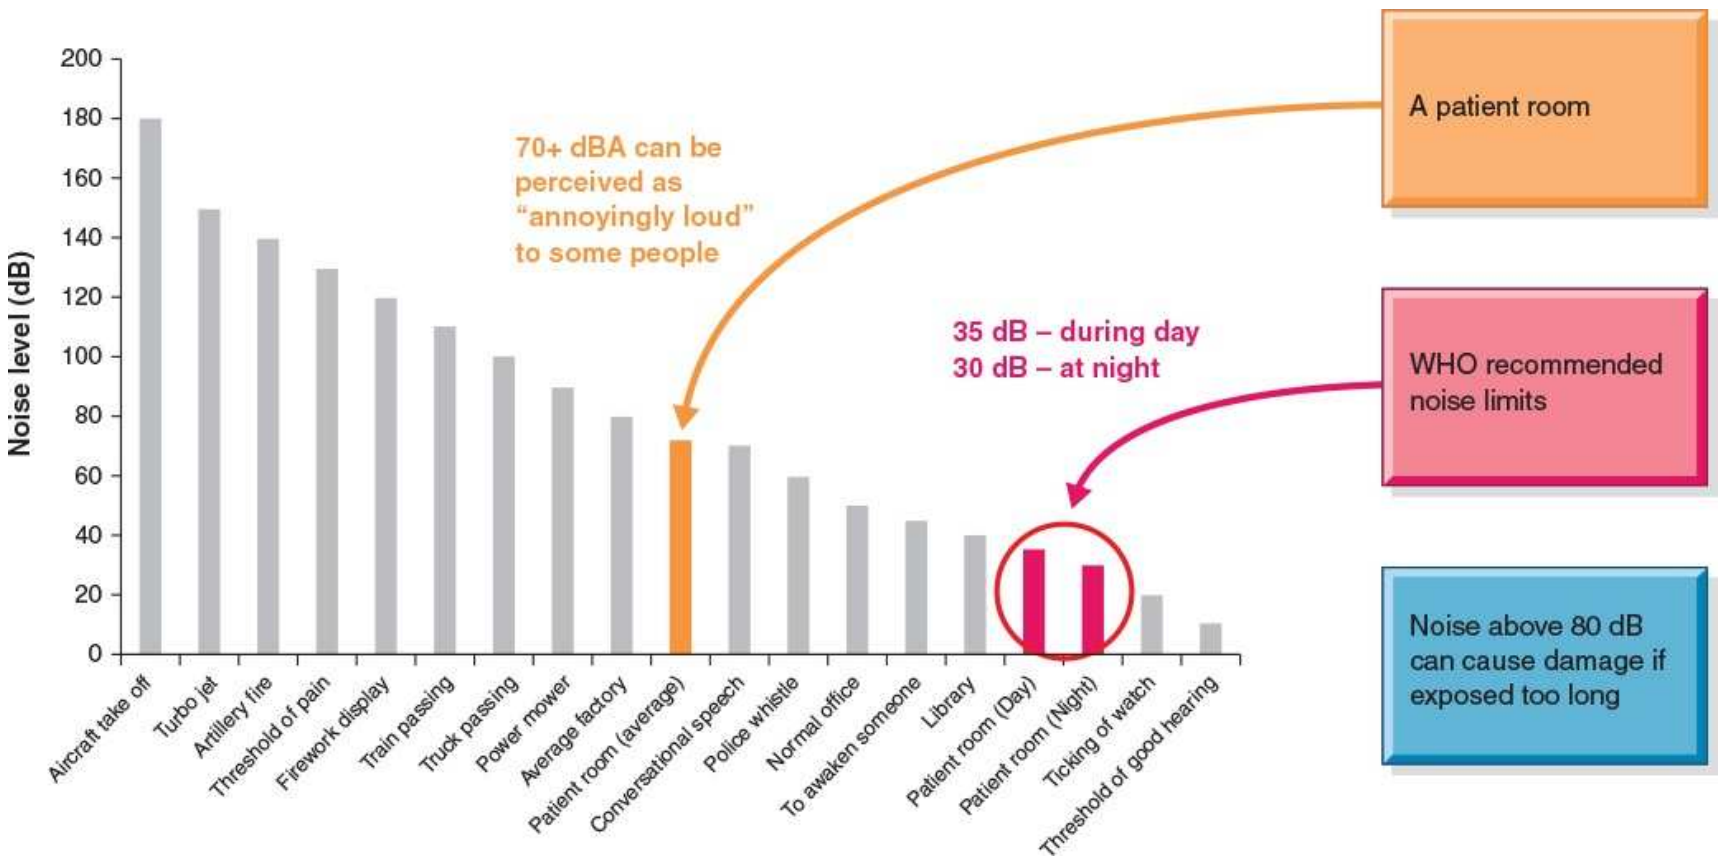

FIGURE 45-3. A noisy hospital room can contribute to patient sensory overload among other problems. (*Source:* Adapted from https://blog.schneider-electric.com/healthcare/2015/05/28/the-hidden-dangers-of-hospital-noise)

Now consider **Ori Soltes**, the young man in the ICU. When assessing Mr. Soltes and his confusion, the nurse needs to be alert for factors that would contribute to sensory overload, such as bright lights, noises from the various monitoring devices, and frequent examinations. In addition, the nurse needs to assess for possible factors contributing to sensory deprivation. For example, the patient is receiving mechanical ventilation. As a result, health care team members may limit verbal communication with the patient, thus reducing some auditory stimuli that he would receive. In addition, the patient is in bed with multiple injuries, also restricting his ability to interact with the environment.

Sensory Deficits

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Impaired or absent functioning in one or more senses is termed **sensory deficit**. Examples of sensory deficits include impaired sight and hearing, altered taste, numbness and paralysis that result in altered tactile perception, and impaired kinesthetic sense. These deficits may be reversible or permanent, may occur gradually or all at once, and may be present at birth or evolve later.

Awareness of a patient's sensory deficits is necessary to determine whether the patient is able to compensate for the deficit. Illness and hospitalization may threaten a patient's usual adaptive patterns and require new self-care abilities. Patients with evolving deficits will require assistance with coping and learning to compensate skillfully.

Think again of **Dolores Pirolla**, the wife of the man with vision and hearing deficits. The nurse needs to assess both the patient and his wife to determine how each is coping. From the description at the beginning of the chapter, Mr. Pirolla appears to be experiencing problems coping with vision changes. As a result, both Mr. and Mrs. Pirolla are beginning to experience social isolation. The nurse would incorporate this information when developing a plan of care for the patient and his wife.

Sensory Processing Disorder

A **sensory processing disorder** is difficulty in the way the brain takes in, organizes, and uses sensory information, causing a person to have problems interacting effectively in the everyday environment (Kranowitz, 2005, p. 68). Children with sensory processing disorders may experience a range of sensory processing issues:

- The child's central nervous system may not receive or detect sensory information.
- The brain may not integrate, modulate, organize, and discriminate sensory messages efficiently.
- The disorganized brain may send out inaccurate messages to direct the child's actions. As a result, the child may not behave in a purposeful way (e.g., they may have trouble listening, paying attention, interacting with others, processing new information, and learning).

It is important for parents, educators, and nurses to identify a child's specific type of processing disorder in order to secure appropriate treatment. See Figure 45-4 for a description of characteristics and signs of common disorders (Kranowitz, 2005).

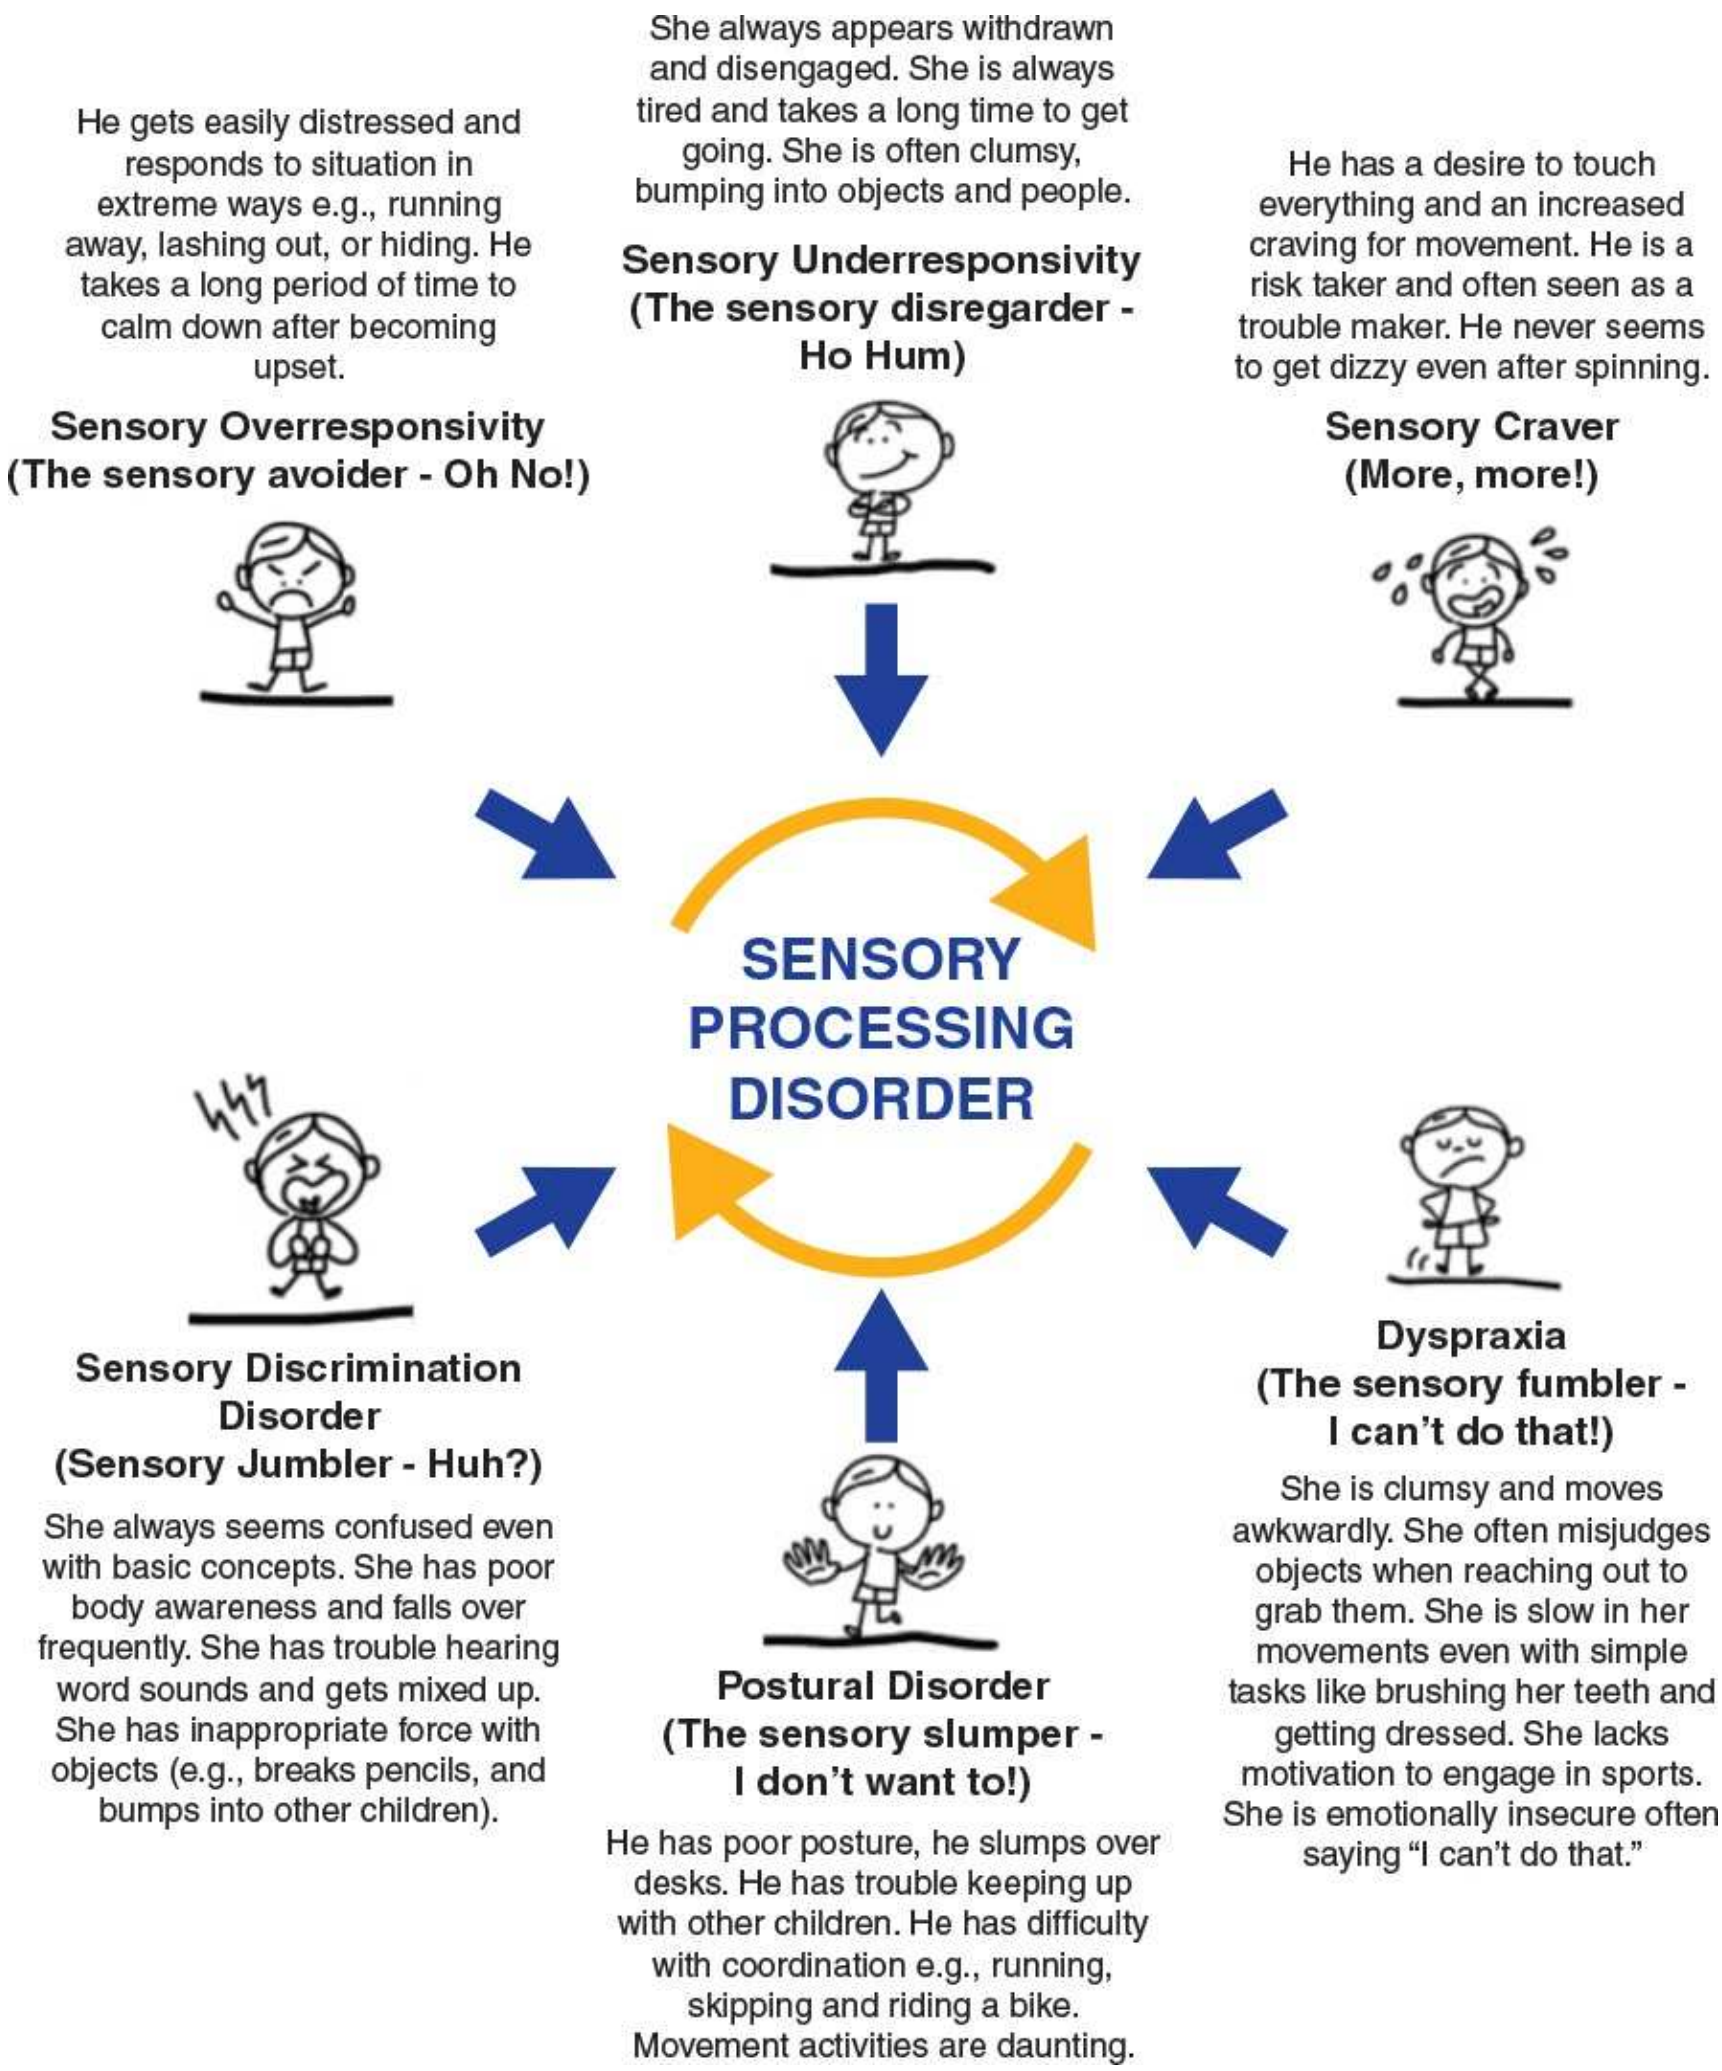

FIGURE 45-4. This poster was designed to guide parents and educators to recognize the characteristics and signs of sensory processing disorder. (*Source:* Reprinted with permission from Emmaly Rowley, Calm the Chaos.)

Sensory Poverty

Diane Ackerman (1990), poet, essayist, and naturalist, believes that we are now living in an age of **sensory poverty**. High-tech devices deliver a bewildering array of assaults on our senses every day. Yet we are learning about our world without experiencing it up close, right here, right now, in "all its messy, majestic, riotous detail." You have probably often heard the advice to stop and take time to smell the roses. But when was the last time you cradled a rose bloom, inhaled its perfume, and marveled at its color? When did you last lie on freshly mown and fragrant grass and look up at the night sky mesmerized by the moon and stars? When did you last marvel at the complex aromas and flavors coming from a new culinary experience? Do you agree with Ackerman that our lives are becoming poorer as we lose the ability to be sensually present in the moment to the world around us? Have you used a mindfulness exercise to enhance a sensory experience?

Kearney (2021) writes in a book on touch that our existence is increasingly lived at a distance. As we move from flesh to image, we are in danger of losing touch with each other and ourselves. How can we combine the physical with the virtual, our embodied experience with our global connectivity? How can we come back to our senses?

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

FACTORS AFFECTING SENSORY STIMULATION

The amount of stimuli different people consider optimal appears to vary considerably. Factors influencing the amount and quality of stimuli needed to maintain cortical arousal include developmental considerations, culture, personality and lifestyle, stress and illness, and medication.

Developmental Considerations

Different types of sensory stimulation are needed for growth as sensory receptors, organs, and the nervous system mature. Although the newborn is capable of rudimentary perceptual discrimination at birth, many neural pathways are immature and must be stimulated to develop, become refined, and function adequately. Appropriate stimulation includes soothing, holding, rocking, and changes of position (tactile and kinesthetic sensations), singing and being talked to (auditory sensations), and changing patterns of light and shade, such as through the use of mobiles and bright objects (visual sensations). On the other hand, the neonatal ICU may be a source of inappropriate sensory stimulation. To facilitate developmentally supportive care, medically fragile infants are recommended to have limited light and visual and vestibular stimulation to simulate being in the womb.

For children, engaging in developmentally appropriate play helps develop muscles and coordination, and provides an outlet for surplus physical energy and the release of emotional energy. Play also provides sources of learning, stimulates creativity, teaches sex roles, and helps with development of communication, social skills, and self-insights.

Sensory functioning tends to decline progressively throughout adulthood as the result of aging or chronic illness. Adults may experience the need to compensate for the loss of one type of stimulation by increasing other sources of sensory stimuli. Touch becomes increasingly important as we age. Paturel (2017) offers the following advice to stimulate touch:

- If you like to dance, then dance. If you like to walk, walk. The more your body has experience of moving in space, the more those receptors will stay active and useful.
- Wear body-hugging clothing to stimulate touch receptors.
- Be generous with physical affection. Hug your spouse, kiss your grandkids, and ask them to reciprocate. Pet the dog. Schedule a massage. Touch boosts well-being and helps you feel in tune with the people around you.

Box 45-4 details sensory changes related to aging. Also see the accompanying display, Focus on the Older Adult: Sensory Functioning on page 1838. Be aware that sensory deprivation, especially in the elderly, can lead to loneliness and social isolation. The National Academy of Sciences, Engineering, and Medicine's (2020) report "Social isolation and loneliness in older adults: Opportunities for health care system" writes that:

- About a quarter of Americans ages 65 years and older are socially isolated, and 43% of those 60 and older report feeling lonely.
- Social isolation contributes to premature death from all causes and increases the dementia risk by 50%.
- Heart failure patients who report feeling lonely are four times more likely to die than those who do not.
- Social isolation or loneliness heightens the risk of coronary heart disease by 29% and risk of stroke by 32%. These problems may be worse for older minorities, immigrants, and those who are lesbian, gay, bisexual, or transgender.

Hammond and Pullen (2020) offer practical strategies for managing loneliness in older adults.

Culture

A person's culture may determine how much sensory stimulation is considered normal. For example, the amount of touching a child experiences in a family that is physically demonstrative may be different from that experienced by a child in a family that is less so. Ethnic norms, religious norms, income group norms, and the norms of subgroups within a culture all influence the amount of sensory stimulation a person seeks and perceives as meaningful.

Moreover, sensory deprivation, sensory overload, and sleep deprivation are all related to or affected by a person's cultural practices, values, and beliefs. The nurse who is sensitive to the patient's culture attempts to determine what constitutes acceptable levels of stimuli from the patient's viewpoint. For example, certain cultures view touching as a natural and welcome custom, whereas other cultures may view it as insulting or offensive. Similarly, patients may find comfort in cultural and religious symbols of care and healing that are absent in a hospital environment. Thus, nurses must be aware of the aspects of the patient's culture to deliver culturally competent care.

Personality and Lifestyle

Apart from a person's culture, different personality types demand different levels of stimulation. One person may thrive on a steady stream of fast-paced changes and excitement, whereas another may feel best when daily routines are rigidly structured, and life sends no challenges necessitating changes. Lifestyle choices can dramatically influence the quantity and quality of stimuli a person receives. The nurse who elects to work in the emergency department of a large city hospital is exposed to stimuli vastly different from those of the nurse making home visits in a rural setting.

Box 45-4 **Sensory Changes Related to Aging**

As a normal part of aging, most older adults will experience some changes in their sensory capacity that can have a severe impact on communication skills. The following are common changes seen with advancing age and the disease states and injuries that occur more frequently in aging.

Vision Changes Common in Older Adults

Presbyopia: A loss of elasticity in the lens of eye leading to a decrease in the eye's ability to change the shape of the lens to focus on near objects such as fine print and decreased ability to adapt to light.

Diseases That Alter Vision Seen More Frequently as People Age

- *Cataracts:* Clouding of the crystalline lens presents as painless, progressive loss of vision; can be unilateral or bilateral.
- *Macular degeneration:* The most common cause of legal blindness in the older adult. The development of drusen deposits in the retinal pigmented epithelium is the leading cause of central vision loss in older adults. More common in fair-haired, blue-eyed people. Other risk factors include smoking and excessive sunlight exposure. There are wet and dry forms of macular degeneration.
- *Glaucoma:* A potentially serious form of eye disease. The majority of cases of glaucoma are open-angle glaucoma (95%). Increased intraocular pressure causing atrophy and cupping of the optic nerve head causing visual field deficits that can progress to blindness. Vision changes include loss of peripheral vision, intolerance to glare, decreased perception of contrast, and decreased ability to adapt to the dark.
- *Diabetic retinopathy:* End-organ damage from diabetes causing retinopathy and spotty vision. Risk can be reduced by tight blood sugar control. Starts as nonproliferative and progresses to proliferative that should be treated with laser photocoagulation.
- *Hypertensive retinopathy:* End-organ damage from poorly controlled hypertension causing background and eventual proliferative retinopathy. Usually treated with laser photocoagulation and tight blood pressure control.
- *Temporal arteritis:* Autoimmune disorder that causes inflammation of the temporal artery. It presents as malaise, scalp tenderness, unilateral temporal headache, jaw claudication, and sudden vision loss (usually unilateral). This vision loss is a medical emergency but is potentially reversible if identified immediately. The patient should see an ophthalmologist, or go to the emergency room immediately if symptoms develop.
- *Detached retina:* Can occur in patients with cataracts or recent cataract surgery, trauma, or be spontaneous. Presents as a curtain coming down across vision. Should see an ophthalmologist or proceed to the emergency room immediately.

Hearing Changes Common in Older Adults

- *Presbycusis:* Loss of high-frequency, sensorineural hearing loss. Has a gradual onset, is progressive, and is bilateral. Due to gradual loss of hair cells and fibrous changes in the small blood vessels that supply the cochlea. Difficulty hearing high-pitched sounds such as *s, z, sh,* and *ch.* Background noise further aggravates hearing deficit.
- *Conductive hearing loss:* Involves the outer and/or middle ear. Causes of conductive hearing impairment include cerumen impactions or foreign bodies, ruptured eardrum, otitis media, and otosclerosis.
- *Sensorineural hearing loss:* Involves damage to the inner ear, the cochlea, or the fibers of the eighth cranial nerve. Causes of sensorineural hearing loss include hereditary causes, viral or bacterial infections, trauma, tumors, noise exposure, cardiovascular conditions, ototoxic drugs, and Ménière disease.

Diseases That Alter Hearing Seen More Frequently as People Age

- *Central auditory processing disorder:* An uncommon disorder that includes an inability to process incoming signals and is often found in stroke patients and older adults with Alzheimer dementia. The person's hearing is intact but their ability to process the sound is impaired.
- *Tinnitus:* Ringing in the ears may fluctuate, can be due to damage to the hair receptors of the cochlear nerve and age-related changes in the organs of hearing and balance. Patients with tinnitus should be referred to ENT.
- *Ménière disease:* Characterized by fluctuating hearing loss, dizziness, and tinnitus. Possible causes of Ménière disease include hypothyroidism, diabetes, and neurosyphilis.

Changes in Smell and Taste Common to Older Adults

- Common changes in smell include a decline in the sensitivity to airborne chemical stimuli with aging.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Common changes in taste include a decreased ability to detect foods that are sweet. Most changes in taste are thought to occur due to decreased sense of smell, medications, diseases, and tobacco use.

Diseases That Alter Smell and Taste Seen More Frequently as People Age

Burning mouth syndrome: This is a sensation that the tongue is tingling or burning. There may be several contributing factors: Vitamin B deficiencies, local trauma, gastrointestinal disorders causing reflux, allergies, salivary dysfunction, and diabetes.

Changes in Peripheral Sensation Common to Older Adults

- Peripheral nerve function that controls the sense of touch declines slightly with age.
- Two-point discrimination and vibratory sense both decrease with age.
- The ability to perceive painful stimuli is preserved in aging. However, there may be a slowed reaction time for pulling away from painful stimuli with aging.

Diseases That Alter Peripheral Sensation Seen More Frequently as People Age

- *Peripheral neuropathy:* Nerve pain in the distal extremities related to nerve damage from circulatory problems or vitamin deficiencies. Common vitamin deficiencies which impact peripheral nerves include B_6, B_{12}, and folate.
- *Diabetic neuropathy:* End-organ damage to the peripheral nerves from microvascular changes which occur with diabetes. Often leads to loss of sensation in the feet of diabetics leading to undetected trauma to the extremities which can lead to refractory infections due to poor vascular supply to the extremity. It is extremely important to teach diabetics and patients with peripheral neuropathy to provide special care to their feet.
- *Phantom limb pain:* The experience of pain that can range from dull ache to crushing pain where an amputated limb once was. The sensory cortex of the brain has influence in this mechanism. This pain is often chronic and requires special interventions to control and manage the pain including electronic prosthetics, analgesics, and psychosocial support.
- *Acute sensory loss:* May be due to a stroke, acute nerve entrapment in the spine, or compartment syndrome due to trauma to a limb. Will present with acute onset of numbness, tingling, or lack of sensation and function in the affected extremity.

Source: Reprinted with permission from Boltz, M., Capezuti, E., Fulmer, T., & Zwicker, D. (2016). *Evidence-based geriatric nursing protocols for best practice* (5th ed.). Springer Publishing Company.

Stress and Illness

Increased sensory stimulation may be sought during periods of low stress simply to maintain cortical arousal. During high-stress periods, multiple stressors may already be overloading the sensory system, and the person desires decreased sensory stimulation. Illness, a time of stress, can affect the reception of sensory stimuli and their transmission and perception. Therefore, the stress of physical illness, pain, hospitalization, testing, surgery, or treatment may provide more stimulation than a person can process and respond to without assistance.

One of the surprising symptoms of COVID-19 that was recognized early was the loss of smell. See the accompanying "Through the Eyes (Nose) of the Patient." While some also reported a loss of taste, Jarvis (2021) explains why this was complicated thanks to a process called oral referral, which causes us to perceive what is happening in the nose as if it were happening in the mouth.

Focus on the Older Adult

SENSORY FUNCTIONING

Age-Related Changes	Nursing Strategies
Decrease in vision	• Ensure that the patient is using corrective lenses such as contacts, glasses, and/or magnifiers. • Administer medications that enhance vision, such as medications that lower intraocular pressure in older adult patients with glaucoma. • Provide adequate lighting and clear pathways of clutter to prevent injury. • Provide enlarged print. • Encourage the patient to visit the ophthalmologist annually.
Decrease in hearing	• Ensure that the patient is using appropriate and functioning hearing

	assistive devices. • When communicating with the patient, use a lower tone. • Speak so that the patient can see your mouth movements. • Explore the use of an approved clear mask or plastic shield so that the patient can see your mouth movements.
Decreased sense of touch	• Protect the patient's skin from temperature extremes. • Assess the extremities for breaks in the skin, blisters, drainage, or open wounds. • Use moisturizers to keep the patient's skin supple. • Ensure that the patient is ambulating with assistive devices. • Use massage, shampoos, foot rubs, etc. as desired by the patient.
Sensory deprivation	• Discourage the use of sedatives. • Assess the effect of medications on the patient's central nervous system. • Provide interaction with children and pets. • Encourage the patient to participate in exercise classes and provide activity therapy. • Ensure that institutionalized older adults share meals with four people per table. • Ensure that homebound older adults have frequent visits from family and community resources such as Meals on Wheels or church volunteers.
Sensory overload	• Orient the patient to person, place, and time. • Decrease environmental noise. • Encourage the patient to participate in nursing care.

Smell is integral to our experience of taste. People often struggle to separate the two, certain that they have lost their sense of taste when the taste buds—which detect only sweet, salty, bitter, sour, and umami flavors—remain fully functional. There was also the question of the sensations we experience through neither olfaction nor taste, but via the nerves of the trigeminal system, the coolness of mint, the spice of peppers, the bubble of carbonation. Were these also affected? (The three, together, are known as our chemosensory senses, those we use to detect the presence of chemicals in our environment [p. 24]).

Through the Eyes (Nose) of the Patient

As the COVID-19 pandemic progressed, many began to talk about a loss of smell and the symptoms—known as parasomnia, incorrect smells; phantosomia, phantom smells—went from nearly unknown to incredibly common.

"I doused a worryingly bland breakfast with hot sauce to no effect."

"Meat smells like it is rotting, and mint toothpaste is so off-putting I had to switch to a bubble gum flavor."

"Nothing is savory anymore, coffee is just bitter, a cake is just sweet, a burger is just salty."

"I [a sommelier] failed to notice that the cat's litter box was full."

"All of a sudden, life is newly dangerous: food poisoning, gas leaks, not noticing that dinner is burning."

"I feel like I'm living my life in black and white, trapped behind a sheet of glass."

"My sense of normalcy and well-being disappeared with my olfaction. I feel alien from myself, detached from normality. Lonely in my body. It's so hard to explain."

"I feel discombobulated—like I don't exist."

As the sense of smell seemed to be returning, many reported something new.

"My sense of smell was coming back broken. Food smells like gasoline or cigarettes, scented body wash was like burning rubber."

"My boyfriend no longer smells or tastes right, and I've begun to avoid kissing him, but I haven't told him why."

"Poo smells better than coffee."

"But what is life without taste, without smell? If I never regain these abilities, will the question 'What do you want for dinner?' mean anything? Will a nice restaurant still have value? How will it feel when someone cooks for me, watches me take the first bite, and waits for my reaction? What is the point of perfume, or piney mountain air?"

Source: These comments are extracted from Chiu, A. (2020, November 5). COVID-19, in addition to stealing sense of smell, may also warp it, *The Washington Post*, p 12; Diamond, K. (2020, September 6). The Strange Grief of Losing My Sense of Taste. *The New York Times*, A23; Jarvis, B. (2021, January 31). The forgotten sense. *The New York*

Times Magazine, pp. 20–25, 46–47, 49.

Lindsay (2021) describes the following smell and taste disorders:

- Anosomia: inability to smell
- Dysomia: altered smell perception
- Hyposomia: decreased ability to smell
- Ageusia: complete loss of taste
- Dysageusia: distorted taste perception
- Hypogeusia: reduced ability to taste

Nomosomia and nomogeusia refer to the normal ability to smell and taste, respectively.

Think back to **Muriel Hao**, the woman who had surgery 2 days ago. Most likely, Ms. Hao is experiencing sensory overload from all of the events of the past several days. The constant beeping of the equipment is adding to this overload.

Medication

Medications that alert or depress the central nervous system may interfere with the perception of sensory stimuli. Narcotics and sedatives decrease awareness of sensory stimuli. Antipsychotics can influence how sensory stimuli are perceived and processed. Certain medications may also contribute to the impairment of sensory functioning by decreasing reception (e.g., captopril, an antihypertensive agent, can cause taste alteration). Examples of medications that are ototoxic and can impair auditory function if taken over a long period of time include furosemide, some cancer chemotherapies, and aspirin. Be sure to review patients' medication records when assessing for sensory alterations.

NURSING PROCESS FOR SENSORY FUNCTIONING

Assessing

When assessing a patient for disturbed sensory perceptions, interview the patient and assess for sensory deficits and manifestations of sensory deprivation or overload. Be sure to include an assessment of the patient's environment to determine whether it is providing adequate sensory stimulation for healthy development.

Identifying At-Risk Patients

Patients may be at risk for sensory disturbances for different reasons. Often there are physiologic reasons that place patients at risk. Aging, for example, is often accompanied by diminished senses. Diseases can also diminish senses. Diabetes-related neuropathies can result in a loss of sensation in limbs, rendering the diabetic unable to feel hot objects such as bath water, which can result in burns. Certain drugs affect taste. Social and environmental factors likewise place people at risk. Humans need appropriate human and environmental stimulation. When either or both are deficient or excessive, problems may result. Lifestyle factors may also place people at risk, such as engaging in work or leisure activities that are potentially harmful to the eyes or ears—for example, exposure to chemicals, flying objects, and loud noises.

With all of us spending more time during the pandemic staring at a computer screen, phone, or other digital device, especially children doing distance learning, more people than ever before are experiencing computer vision syndrome (CVS), or digital eye strain. Symptoms of CVS include eye fatigue and discomfort, dry eyes, headaches, blurred vision, neck and shoulder pain, eye twitching, and red eyes. All About Vision suggests these 10 easy steps you can take to reduce your risk of eye strain and other common symptoms of CVS. See Box 45-5.

Assessment of the Sensory Experience

When assessing a patient's sensory experience, structure the history using the components of the sensory experience—stimulation, reception, and transmission–perception–reaction (see Focused Assessment Guide 45-1 on pages 1842–

1843). Because patients may adapt to sensory impairments, it may be helpful to include someone the patient knows well (e.g., a partner or parent) in the assessment to see if that person has noticed behavioral characteristics in the patient that suggest a sensory disturbance (e.g., "I've noticed he turns the television volume much louder than ever before."). Also, recognize that people may develop acuity in certain senses to compensate for losses in others. For example, many people who are blind have acute hearing. Begin by asking patients to evaluate their sensory functioning: "How would you rate your vision (hearing, and the like): Excellent, good, fair, poor, or bad?"

The mental status exam is included in assessments of sensory functioning. Chapter 27 provides a detailed description of how to assess levels of awareness (also see Box 45-2 on page 1831), levels of consciousness, memory, abstract reasoning, and language. The Mini-Mental State Examination (MMSE), available at https://www.dementia.org/diagnosing-dementia-mini-mental-status-exam, is one of the most widely used clinical instruments for quickly detecting cognitive impairment and assessing its severity, as well as for monitoring cognitive changes over time.

STIMULATION

Assess for any recent changes in sensory stimulation, for example, reduction of stimulation from one or more sensory modalities ("Since my husband died, no one touches me anymore. It sounds crazy, but I'm hungry to be touched!") or new or unusual stimulation ("Ever since my granddaughter moved in with me, my house is always noisy. I can't stand the constant noise and her smoking."). Assess whether the type of stimulation present is developmentally appropriate. Patients at high risk for problems related to stimulation include children in nonstimulating environments, older people, terminally ill patients, patients on bed rest, patients in isolation, and patients requiring intensive nursing in a critical care setting.

RECEPTION

Assess for anything that may interfere with sensory reception and identify any corrective devices the patient uses for sensory impairments, such as eyeglasses, contact lenses, or hearing aids. If corrective devices are necessary, assess whether the patient is actually using them, has the proper equipment, and understands related care. For example, ask the patient, "When were your eyes last examined?" or "Are there batteries for your hearing aid?" The reception section of the Focused Assessment Guide 45-1 (on page 1842–1843) highlights assessment strategies for each sense. Patients at high risk for reception problems include people with visual, auditory, or other sensory impairments.

Box 45-5 Computer Eye Strain: 10 Steps for Relief

Get a comprehensive eye exam	Having a routine comprehensive eye exam every year is the most important thing you can do to prevent or treat computer vision problems. During your exam, be sure to tell your eye doctor how often you use a computer and digital devices at work and at home. Measure how far your eyes are from your screen when you sit at your computer, and bring this measurement to your exam so your eye doctor can test your eyes at that specific working distance.
Use proper lighting	Eye strain often is caused by excessively bright light either from outdoor sunlight coming in through a window or from harsh interior lighting. When you use a computer, your ambient lighting should be about half as bright as that typically found in most offices. Eliminate exterior light by closing drapes, shades, or blinds. Reduce interior lighting by using fewer light bulbs or fluorescent tubes, or use lower-intensity bulbs and tubes. Also, if possible, position your computer screen so windows are to the side, instead of in front or behind it. Many computer users find their eyes feel better if they can avoid working under overhead fluorescent lights. If possible, turn off the overhead fluorescent lights in your office and use floor lamps that provide indirect "soft white" LED lighting instead.
Minimize glare	Glare from light reflecting off walls and finished surfaces, as well as reflections on your computer screen also can cause computer eye strain. Consider installing an antiglare screen on your display and, if possible, paint bright white walls a darker color with a matte finish. If you wear glasses, purchase lenses with antireflective (AR) coating. AR coating reduces glare by minimizing the amount of light reflecting

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

	off the front and back surfaces of your eyeglass lenses.
Upgrade your display	If you have not already done so, replace your old tube-style monitor (called a cathode ray tube or CRT) with a flat-panel LED (light-emitting diode) screen with an antireflective surface. When choosing a new flat panel display, select a screen with the highest resolution possible. Resolution is related to the “dot pitch” of the display. In general, displays with a lower dot pitch have sharper images. Choose a display with a dot pitch of .28 mm or smaller. Also, choose a relatively large display. For a desktop computer, select a display that has a diagonal screen size of at least 19 inches.
Blink more often	Blinking is very important when working at a computer; blinking moistens your eyes to prevent dryness and irritation. When staring at a screen, people blink less frequently—only about one third as often as they normally do—and many blinks performed during computer work are only partial lid closures, according to studies. Tears coating the eye evaporate more rapidly during long nonblinking phases and this can cause dry eyes. Also, the air in many office environments is dry, which can increase how quickly your tears evaporate, placing you at greater risk for dry eye problems. If you experience dry eye symptoms, ask your eye doctor about artificial tears for use during the day. To reduce your risk of dry eyes during computer use, try this exercise: Every 20 minutes, blink 10 times by closing your eyes as if falling asleep (very slowly). This will help rewet your eyes.
Exercise your eyes	Another cause of computer eye strain is focusing fatigue. To reduce your risk of tiring your eyes by constantly focusing on your screen, look away from your computer at least every 20 minutes and gaze at a distant object (at least 20 feet away) for at least 20 seconds. Some eye doctors call this the “20-20-20 rule.” Looking far away relaxes the focusing muscle inside the eye to reduce fatigue. Another exercise is to look far away at an object for 10 to 15 seconds, then gaze at something up close for 10 to 15 seconds. Then look back at the distant object. Do this 10 times. This exercise reduces the risk of your eyes’ focusing ability to “lock up” (a condition called accommodative spasm) after prolonged computer work. Both of these exercises will reduce your risk of computer eye strain. Also, remember to blink frequently during the exercises to reduce your risk of computer-related dry eye.
Take frequent breaks	To reduce your risk for computer vision syndrome and neck, back, and shoulder pain, take frequent screen breaks during your workday (at least one 10-minute break every hour). During these breaks, stand up, move about and stretch your arms, legs, back, neck, and shoulders to reduce tension and muscle fatigue.
Modify your workstation	If you need to look back and forth between a printed page and your computer screen, place the written pages on a copy stand adjacent to your screen. Poor posture also contributes to computer vision syndrome. Adjust your workstation and chair to the correct height so your feet rest comfortably on the floor. Position your computer screen so it’s 20 to 24 inches from your eyes. The center of your screen should be about 10 to 15 degrees below your eyes for comfortable positioning of your head and neck.
Consider computer glasses	For the greatest comfort at your computer, you might benefit from having your eye doctor modify your eyeglasses prescription to create customized computer glasses. This is especially true if you normally wear contact lenses, which may become dry and uncomfortable during extended screen time. Computer glasses also are a good choice if you wear bifocals or

progressive lenses, because these lenses generally are not optimal for the distance to your computer screen.

Also, you may want to consider photochromic lenses or lightly tinted lenses for computer eyewear to reduce your exposure to potentially harmful blue light emitted by digital devices. Ask your eye doctor for details and advice.

Focused Assessment Guide 45-1

SENSORY STIMULATION

Factors to Assess	Questions and Approaches
Stimulation	"Does your current environment overly, insufficiently, or appropriately stimulate you?" "Are you bored? Why?" "Are you able to read? Watch television? Knit? Why not?" "Are there other people in your home during the day? Do you spend much time together? How do you spend the time?" "Who visits you while you are in the hospital?" Note reduction in the patterns or meaningfulness of stimulation in each sensory modality, changes in stimulation other than decreases (e.g., new or unusual stimulation), or developmental appropriateness of stimulation.
Reception	"Does anything interfere with the functioning of your senses?" (You may need to list these.) "Describe any corrective devices you use for sensory impairments."
Visual disturbances	"Please read my name tag (or this page of print)." Note if the patient can correctly identify objects directly in front of the eyes as well as those requiring peripheral vision. Note eye rubbing, squinting, movements indicating faulty vision (bumping into furniture, overreaching or underreaching for objects), changes in the appearance of the eye (cataracts, swelling), and complaints of eye pain, spots, halos, or other visual disturbances.
Auditory disturbances	"Repeat the words that I will speak softly close to each ear." Note if the patient is able to hear equally well from both ears, distinguish voices, locate the direction of a sound; if the patient needs to face the person speaking and relies on lip reading; if the patient's responses to questions include blank looks, many nods, smiling, or inappropriate responses indicating faulty hearing. Note complaints of ringing or buzzing in the ears.
Gustatory (taste) disturbances	"Close your eyes, stick out your tongue, and tell me if what I place on your tongue is sweet, sour, bitter, salty or umami." "Have you been experiencing any strange tastes (bitter, metallic) or aftertastes lately?" Note if the patient is able to differentiate sweet, sour, bitter, salty or umami tastes or reports unusual, persistent taste sensations. Note deficient oral hygiene, ill-fitting dentures, braces, or anything else that might contribute to gustatory disturbances.
Olfactory (smell) disturbances	"Close your eyes and tell me what you smell." "Have you smelled odors lately that others cannot smell, or have you been especially sensitive to odors?" Note if the patient can correctly identify common odors (coffee, vanilla) or has noticed increased sensitivity to odors.
Tactile (touch) disturbances	"Close your eyes and tell me when you feel something (brush skin with cotton ball), if what you feel is dull or sharp (use both ends of a safety pin), hot or cold (use items from the food tray). Now, keep your eyes closed and tell me what I am placing in your hand (coin, cotton ball, paper clip)." Note if the patient can correctly sense touch and distinguish sharp and dull, hot and cold, and different shapes. Note if the patient reports decreased sensation in any part of the body; numbness, pins, and needles; tingling or abnormal sensitivity to pain or touch.
Kinesthetic and visceral disturbances	Note if the patient withdraws from being touched. "Have you noticed any changes in the way you perceive your body?" "Do you feel any unusual pressure or pain inside your body?" Note if the patient seems unsure of their body parts or body position and if the patient experiences new internal sensations (fullness, pressure, pain).
Transmission–perception–reaction	"Are you aware of any problems with your nervous system?" "Have you found it difficult to communicate verbally?" Note consciousness, orientation, appropriateness of responses, ability to perform usual self-care activities, ability to follow simple commands, decision-making abilities, pathology affecting the central nervous system, or prescribed or recreational drug use that affects the central nervous system.
Behavioral manifestations of sensory deprivation or overload	
Perceptual responses	Mild to gross sensory distortions (illusions, hallucinations)
Cognitive responses	Thought disorganization, slowness of thought, decreased attention/concentration, difficulty with problem solving and task performance

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Emotional responses	Rapid mood changes, anxiety, panic

Consider **Dolores Pirolla**, and her husband who has visual and hearing deficits. The nurse needs to assess the amount and type of stimulation Mr. Pirolla is receiving. In addition, the nurse needs to investigate what measures the couple uses to adapt to the progressive visual changes. Doing so would provide a sound basis on which to build the care plan. See Box 45-6 for sample documentation of Mr. Pirolla's assessment of sensory functioning.

TRANSMISSION–PERCEPTION–REACTION

Be alert for patients at high risk for transmission–perception–reaction problems, such as the patient who is confused or who has a nervous system impairment. Use everyday interactions as multiple opportunities to assess patients' abilities to transmit, perceive, and react to stimuli.

SIGNS AND SYMPTOMS OF SENSORY DEPRIVATION AND OVERLOAD

Complete the assessment of the patient's sensory functioning by assessing for specific indicators of sensory deprivation or overload (see Box 45-2). Observe for boredom, inactivity, slowness of thought, daydreaming, increased sleeping, thought disorganization, anxiety, panic, illusions, and hallucinations. Know the patient's usual state so that you can identify changes stemming from sensory deprivation or overload.

Think back to **Muriel Hao**, the woman who had surgery 2 days ago. The patient's complaints of being unable to rest because of the machine's beeping should alert the nurse to the possibility of sensory overload. To confirm the suspicion, the nurse needs to review the patient's medical record to gather more data about the patient's usual state and behavior.

Physical Assessment

Physical examination skills related to the senses are discussed in Chapter 27. Ear and eye tests, whether performed by a physician or nurse, should be considered when planning care. Problems with the neurologic system require further assessment of the sensory experience (Fig. 45-5 on page 1844).

Assessment of the Ability to Perform Self-Care

Alterations in sensory functioning may limit a person's ability to perform everyday activities safely. Exercise empathy by trying to imagine how you would get through a day if you lacked sight, hearing, or other senses. Ideally, this exercise will help you fashion a care plan responsive to the needs of patients. Patients with new sensory alterations and their family caregivers need to be instructed about practical ways to modify their home environment for safety. In addition, recognize that patients who are out of their home environment need to be oriented to their new surroundings. Patients need to know how to call the nurse, how to use the lights and television, and how to navigate safely to the bathroom. Before leaving a patient's room, do a quick check to ensure that the environment is safe—especially for patients with sensory impairments.

Box 45-6	**Sample Documentation of a Targeted Assessment**

Mr. Anthony Pirolla came to the clinic with his wife who reported a new concern about his hearing.

Chief complaint: Difficulty hearing.

Signs and symptoms: According to his wife, Mr. Pirolla frequently fails to answer her questions or answers inappropriately. She also reports that he plays the radio and television louder than before. He complains that people seem to be "mumbling" more than usual—especially in church. Patient denies ringing or buzzing in ears.

Onset/duration: Mr. Pirolla states that he has had difficulty hearing since Christmas (2 months ago)—when the whole family came to visit. Mrs. Pirolla believes he had difficulty starting in the summer.

Predisposing factors: In his youth, Mr. Pirolla worked construction and was frequently around loud equipment. He is 77.

Effect on patient: Patient no longer enjoys going out or being with friends and has become more reclusive.

Self-remedies: None.

Intervention: Referred Mr. Pirolla to the clinic's audiologist.

02/24/24
C. Taylor, RN

FIGURE 45-5. Preventive care such as hearing screenings and comprehensive eye exams are critical for finding sensory disorders early.

Diagnosing Actual or Potential Health Problems and Needs

An assessment of sensory functioning may lead to the identification of one or more actual or potential health problems and needs. Following the formulation of the actual or potential health problems and needs, the nurse communicates findings to other nursing and health care professionals through the use of the written and spoken word. The written actual or potential health problem or need becomes a permanent part of the patient's health record.

The International Classification for Nursing Practice (ICNP) identifies several actual or potential health problems related to sensory functioning that may be identified by nurses, among them Impaired Cognition, Confusion, Impaired Memory, Risk for Delirium, Disorientation, and Altered Perception. Different types of Sensory Deficits are among the most common. A sensory deficit is a state in which a person or group experiences or is at risk for a change in the amount, pattern, or interpretation of incoming stimuli. These alterations may be further specified as visual, auditory, gustatory, olfactory, tactile, or kinesthetic. Sensory deprivation, sensory overload, and uncompensated sensory loss may also be used to further specify the disturbed sensory perception and in some cases may be the etiology.

Common etiologies for disturbed sensory perception include the following:

- Altered environmental stimuli: excessive or insufficient
- Altered sensory reception, transmission, or integration
- Chemical alterations: endogenous (e.g., electrolytes) or exogenous (e.g., drugs)
- Psychological stress

Common etiologic factors and potential signs and symptoms for some of these health problems are found in the accompanying box, Examples of Actual or Potential Health Problems and Needs: Sensory Deficits.

Because disturbed sensory perceptions affect many other areas of human functioning, they serve as etiologies for multiple problem statements. Examples may include the following:

- Activity intolerance related to impaired balance and coordination (kinesthetic alteration)
- Anxiety related to paranoia stemming from hearing impairment, sensory deprivation (specify setting), sensory overload
- Communication barrier related to difficulty receiving, transmitting, and perceiving sensory stimuli
- Ineffective coping related to sensory overload (multiple stressors)
- Deficient diversional activity related to impaired vision or hearing
- Delayed growth and development related to nonstimulating home environment

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Impaired physical mobility related to impaired balance and coordination (kinesthetic alteration)
- Impaired parenting associated with failure to provide stimuli for growth related to lack of knowledge, decreased motivation to provide for child's growth and development
- Impaired health maintenance (specify) related to visual impairment, auditory impairment, tactile impairment
- Ineffective role performance related to sensory/perceptual alteration (blindness, deafness, and so forth)
- Sexual dysfunction related to decreased sensation
- Impaired skin integrity related to absent tactile sensation (injury)
- Disturbed sleep pattern related to sensory deprivation or overload
- Impaired social Interaction related to inability to receive and process interactional stimuli
- Social isolation related to visual or auditory impairment
- Disorientation (specify illusions, hallucinations, decreased attention or concentration, and the like) related to sensory deprivation or overload

Outcome Identification and Planning

In all settings in which nurses care for patients, optimal sensory stimulation is a priority. Nursing care focuses on the following patient outcomes:

The patient will:

- live in a developmentally stimulating and safe environment.
- exhibit a level of arousal that enables the brain to receive and meaningfully organize patterns of stimulation.
- demonstrate intact functioning of the senses: vision, hearing, taste, smell, touch, and kinesthetic and visceral awareness.
- schedule appropriate health screening exams for sensory functioning.
- maintain orientation of time, place, and person.
- respond appropriately (verbally and nonverbally) to sensory stimuli while executing self-care activities.

Patients with impaired sensory functioning require individualized outcomes similar to the following:
The patient will:

- report feeling safe and in control of the environment.
- describe different types of meaningful stimuli present in the environment.

Examples of Actual or Potential Health Problems and Needs

SENSORY FUNCTIONING

Actual or Potential Health Problem	Possible Etiologic Factors	Signs and Symptoms
Impaired vision	Eye patches after surgery	"I never realized before how sight-dependent I am. I don't know what time of day it is now unless I have the radio on or smell food coming in." "It's frightening not to know who is in my room and what they are doing." Patient observed sitting in room with blank facial expression; frequently comments on how bored they are and how slowly time is passing; hesitant to move about room without assistance despite having been oriented repeatedly.
Impaired hearing	Effects of aging	"You're right. I don't always hear what people are saying anymore so I try not to get involved in conversations. If people insist on talking, I just nod and hope I'm giving the right response." Able to hear moderately spoken word close to right ear; cannot hear same from left ear; often startled when someone approaches from left side. Sits close to television and radio; loud volume,

		no history of hearing testing.
Impaired taste	Chemotherapy	"I always seem to have a bitter taste in my mouth now and can't stomach certain foods at all that I used to enjoy, like beef, tomatoes, coffee…. I also can't take sweets, and I used to be a real sweets junkie." "Sometimes the very smell of certain foods or even the thought of eating nauseates me." Patient has been receiving vincristine (cancer chemotherapeutic agent) for past 3 months; some nausea and vomiting; history of poor oral hygiene.
Impaired tactile perception	Psychological stress	"I don't know why I feel this way, but I'm hypersensitive to touch. If anyone even brushes against me, I feel burning pain. Even the weight of my clothes against my skin bothers me. I'm trying to move my body as little as possible and keep it protected—but that's obviously impossible when even a breeze assaults me." Patient observed holding the body stiffly looking like they do not know what to do with their arms and legs; dressed only in a loose-fitting outfit; reports sitting at home all day afraid to go out.
Impaired kinesthetic functioning	Clinitron bed therapy	"I've been in this bed for 2 weeks now and I've lost all sense of my body… it's a curious weightless feeling that I have … sort of like floating in Jell-O. I'm no longer sure where my body begins and ends, and when I try to lift an arm or leg, I feel like I'm in slow motion. I hope I'll be able to walk when I get out of here."
Sensory deprivation	Isolation	"One of the worst things that has happened to me since I found out I had COVID-19 is that everyone is afraid of me—and no one touches me. I'm so lonely. I've always needed a lot of people around." "Here in the hospital, I think I'm going crazy. I can't leave this room. Everyone who comes in looks the same, dressed in those yellow gowns. Lately, I've seen some bizarre things that I know can't be real. I look at the clock and it turns into a swirling sun with a sad face that keeps coming closer and closer to me and I'm terrified I'll burn up if it gets too close. That's crazy, isn't it? I'm really losing it now." Disturbed sleep for past 2 weeks; during the day, yawns excessively and catnaps; limited attention span; states they are unable to concentrate on anything.
Sensory overload	Trauma of rape and aftercare	"When is everyone going to stop touching me? First, he wouldn't stop. Now, everyone here is poking at me, looking at me, asking me hundreds of questions…. Why did I have to report this and come to the hospital? Oh, please leave me alone. Get out of here, everyone."

Source: International Council of Nurses. (2019). *Nursing diagnosis and outcome statements*. International Classification for Nursing Practice (ICNP) Catalogue. https://www.icn.ch/sites/default/files/inline-files/ICNP2019-DC.pdf

- demonstrate (describe) appropriate self-care behaviors for visual impairment, hearing impairment, or other sensory impairment.
- verbalize acceptance of the sensory deficit.

Implementing

The nurse can assist patients to improve sensory functioning by teaching them and their significant others some methods for stimulating the senses; teaching patients with intact and impaired senses, appropriate self-care behaviors; and interacting therapeutically with patients experiencing sensory impairments. Safety is always a special concern for patients with sensory alterations. Ensure that the patient's environment is as free of danger as possible, and assist the patient to develop new self-care behaviors to compensate for sensory impairments. Safety considerations are discussed in Chapter 28 in more detail. The nursing interventions described here relate to preventing sensory alteration, stimulating the senses, meeting the needs of vision- and hearing-impaired people, communicating with a confused person, and communicating with an unconscious person. Communication guidelines for patients with sensory deficits are also highlighted in Chapter 8.

Preventing Disturbed Sensory Perception and Stimulating the Senses

Prevention is the most effective means to manage sensory alteration. The key to prevention is to create a functional and meaningful environment with the patient's help, while keeping limitations in mind. The creation of such an environment requires careful observation, analysis, and creative planning.

Although numerous nursing measures can be considered when planning care, their appropriateness depends on the circumstances. Promote the patient's well-being by offering care that provides rest and comfort (see Chapters 35 and 36). Attempt to control patient discomfort whenever possible.

Recall **Muriel Hao**, the woman who had surgery 2 days ago. The patient verbalizes an inability to rest because of the "beeping of the machine." The initial priority is to stop the machine from beeping. The nurse needs to investigate the underlying problem related to the machine's beeping, such as a low battery or an occlusion. The nurse can then focus on comfort measures.

Be aware of a patient's need for sensory aids and prostheses, such as eyeglasses, contact lenses, hearing aids, dentures, canes, and artificial limbs, ensuring that they are available as needed. See the accompanying Research in Nursing box to see how one group of nurses organized to meet the needs of visually impaired people (VIPs) in the hospital. Social activities help stimulate the senses and mind (Fig. 45-6). Enlist the aid of family members to participate in or encourage these activities. Also encourage physical activity and exercise, which help maintain normal sensory perceptions and decrease the likelihood of sensory alteration. (Exercises are discussed in Chapter 34.)

Research in Nursing

Bridging the Gap to Evidence-Based Practice

Caring for Visually Impaired Patients in the Hospital

People with low vision may understandably experience anxiety, fear, and depression when seeking health care.

Related Research

Carlson, C., Howe, T., Pedersen, C., & Yoder, L. H. (2020). Caring for visually impaired patients in the hospital: A multidisciplinary quality improvement project. *American Journal of Nursing*, *120*(5), 48–55.

A group of nurses did a literature search on the needs of visually impaired people (VIPs) but could not find a

comprehensive program that health care facilities could use to meet the needs of this vulnerable population. The aims of this study were to determine the needs of hospitalized VIPs, develop educational and other resources that would help clinicians and other ancillary hospital staff in their interactions with VIPs, and assemble a toolbox of useful materials for VIPs themselves. The team conducted an education program, developed bracelets and room identifiers to alert staff to VIPs needs, introduced a braille version of the hospital menu, and provided VIP toolboxes at each nurses' station. Patient and staff member responses were overwhelmingly positive.

Relevance to Nursing Practice

Provide stimulation for as many senses as possible. Sights, sounds, smells, body positions, and textures help provide a variety of sensations. For example, music therapy has been found to benefit select physiologic variables such as pulse rate, respiratory rate, and mood state in patients receiving mechanical ventilation. Listening to music can ameliorate the stress response and promote nonpharmacologically induced relaxation for the study subjects. All nurses, especially critical care nurses, can confidently implement this nonpharmacologic, independent intervention to promote relaxation without concern about the untoward side effects sometimes caused by pharmacologic sedation (see the next Research in Nursing box). Consider cultural factors when stimulating the patient's senses and when offering nursing care, especially when caring for patients from cultures different from your own (see Chapter 29 for a discussion of common complementary and alternative therapies).

TEACHING ABOUT SENSORY EXPERIENCES

Teaching is a significant nursing responsibility that helps prepare patients for sensory experiences. An informed patient is better able to handle fears, frustration, and confusion. Therefore, explain procedures before performing them or having the patient experience them. Explanations also help prevent patients feeling that their personal space and body are being invaded.

Research in Nursing

Bridging the Gap to Evidence-Based Practice

Music, Sleep, and Well-Being

Adequate sleep is a critical component of illness recovery, and the majority of hospitalized patients, especially those in critical care, experience difficulty sleeping. These sleep disturbances may endure beyond hospitalization. Researchers are now seeking nonpharmacologic interventions to address these and other disturbances.

Related Research

Golilno, A. J., Leone, R., Gollenberg, A., Christopher, C., Stanger, D., Davis, T. M., Meadows, A., Zhang, Z., & Friesen, M. A. (2019). Impact of an active music therapy intervention on intensive care patients. *American Journal of Critical Care*, *28*(1), 48–55.

This study examined the effect of an active music therapy intervention on physiologic parameters and self-reported pain and anxiety levels of patients in the intensive care unit. The study was conducted using a pretest–posttest, within-subject, single-group design. The study population consisted of a convenience sample of 52 patients. Study participants received a 30-minute music therapy session consisting of either a relaxation intervention or a "song choice" intervention. The music therapist recorded the patients' vital signs before and after the intervention, and patients completed self-assessments of their pain and anxiety levels before and after the intervention. After the intervention, significant decreases were found in respiratory rate, breaths per minute, heart rate, and self-reported pain and anxiety levels. No significant change in oxygen saturation level was observed. Outcomes differed between the two intervention groups: patients receiving the relaxation intervention often fell asleep.

Hetland, B., Lindquist, R., Weinert, C. R., Peden-McAlpine, C., Savik, K., & Chlan, L. (2017). Predictive associations of music, anxiety, and sedative exposure on mechanical ventilation weaning trials. *American Journal of Critical Care*, *26*(3), 210–220.

In this study of 307 patients, listening to music, anxiety levels, and sedative exposure did not influence time to initial weaning trial or duration of trials. Clinical factors of illness severity, days of weaning trials, and tracheostomy placement influenced weaning patterns in this sample.

Bush, H. I., LaGasse, A. B., Collier, E. H., Gettis, M. A., & Walson, K. (2021). Effect of live versus recorded music on children receiving mechanical ventilation and sedation. *American Journal of Critical Care*, *30*(5), 343–349.

Relevance to Nursing Practice

Listening to music is an inexpensive intervention without negative effects. Prospective studies of music intervention and other psychophysiologic factors are needed to determine best practices to address sleep disturbances and facilitate physiologic outcomes and well-being.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Allow patients experiencing perceptual and thought distortions the opportunity to acknowledge that fact. Discussing such experiences and reassuring the patient that these experiences are normal and usually temporary generally eases anxiety.

FIGURE 45-6. The nurse helps the patient find methods for stimulating the senses. Family members may participate in sensory activities.

Remember **Ori Soltes**, the young man in the ICU who becomes confused. The nurse needs to acknowledge the patient's confusion, reorienting him frequently. In addition, the patient's ability to communicate is limited because of the ventilator. Therefore, the nurse should provide the patient with alternative means to communicate, such as paper and pencil or a blackboard to write on, to make his needs known. The nurse also needs to reinforce explanations about all the equipment and technologies to which the patient is being exposed, to help alleviate some of his anxiety.

Patients and family members can be guided in sensory self-stimulation, and parents can be aided in stimulation of newborns, infants, and children. The Teaching Tips 45-1 (on page 1848) display gives helpful suggestions for teaching patients about protecting and stimulating sensory function and includes suggestions that the nurse can use in a variety of situations. Table 45-1 (on page 1849) provides additional information on stimulating the senses for patients and nurses.

Teaching Tips 45-1

SENSORY FUNCTIONING

Health Topic	Teaching Tip	Why Is This Important?
Hearing	• Avoid loud noise that is concentrated at the ear canal, such as with earphones. • Decrease background or loud noises. • Use earplugs when using loud machinery, including lawn mowers, grass trimmers, or industrial equipment. • Have regular hearing assessments. Children should be assessed in school yearly. • Do not insert objects such as cotton-tipped applicators into the ear. • Do not clean inside the ear. • Have ear pain evaluated by a physician or	Hearing loss occurring as a person ages is called presbycusis. Presbycusis involves the deterioration of nerves and structures within the inner ear. Many occupations result in hearing loss due to increased noise. Thus, the use of ear-protective devices can decrease the development of hearing loss. Instructing the patient on signs and symptoms of hearing loss and interventions to be implemented

	nurse practitioner. • Be aware of the signs and symptoms of hearing loss.	can help to slow the development of hearing loss.
Vision	• Protect the eye from damage due to ultraviolet rays with sunglasses and tinted windows. • Provide adequate light for working or reading. • Stimulate vision with colors and shapes. • Use large print to assist in readability. • Have an annual eye examination. • Do not rub the eyes. • Use cleaning products or aerosol products safely in a well-ventilated area. • Use eye shields when in contact with harmful or toxic products, such as blood or body fluids or cleaning products. • Do not use nonprescription eye drops.	The education of the patient to maintain adequate eye function enhances the patient's quality of life. The avoidance of strain on the eye stimulates vision, thus enhancing sensory perception.
Taste (gustatory)	• Practice oral care three times per day to prevent infection and decay. • Visit the dentist biannually for dental cleaning and examination. • Notify the dentist about pain or sensitivity to hot or cold. • Provide nutritional foods that are high in fiber, and low in fat and sugar. • Enhance taste with the use of spices.	Prevention of mouth disease enhances the taste and enjoyment of foods.
Smell	• Use aromatherapy to reduce stress. • Protect the nose from noxious fumes. • Eliminate disturbing odors with adequate ventilation. • Visit the physician or nurse practitioner when experiencing nasal congestion or diminished sense of smell. • Do not wear heavy colognes or perfumes. • Enhance the sense of smell by remembering pleasant odors.	The sense of smell is important in assisting the person to relax, particularly during times of stress. It is important to evaluate any difficulty with the sense of smell and nasal congestion, since the nose lies in close proximity to the ear and the brain. Thus, the prevention of infection is a primary aspect of care.
Touch	• Protect the skin from extremes in temperature. • Provide various textures in the environment. • Provide touch such as during the bath or massage therapy. • Instruct on all aspects of invasive procedures.	Protecting the skin from temperature changes decreases damage to the skin and underlying tissues. The use of a variety of textures stimulates nerve fibers and tactile sense.
Sensory Overload	• Reduce the number and type of stimuli. • Provide periods of rest. • Provide explanation of sounds and activities within the environment. • Use relaxation techniques to enhance rest.	Sensory overload can be prevented by using these measures. As a result, the patient is able to organize stimuli to decrease anxiety and stress.
Sensory Deprivation	• Provide reading material, audiovisual stimulation, and interactive activities. • Provide stimulation through visitors, phone conversations, and e-mail. • Use therapeutic touch. • Encourage the use of assistive devices such as hearing aids and glasses.	Increasing sensory perception enhances the patient's responses, helping to create a meaningful environment.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Provide a radio and television.
- Orient to time, place, and person.

Table 45-1 Stimulating the Senses

SENSE	TEACHING PATIENTS	NURSING INTERVENTIONS
Vision	Surround yourself with different colors and with an environment that changes (walk through a mall, sit by a window where you see people come and go). Develop a sensitivity to changes in nature (weather patterns, dawn-to-night cycle, changing seasons, changes in a plant or animal). Use visual devices to keep oriented (watches, calendars, newspaper, television). Use crossword puzzles and games to stimulate mental activities. Create favorite scenes in your mind, paying attention to tiny details.	Wear visually stimulating and comforting colors. Keep meaningful visual stimuli such as photos, greeting cards, toys, or flowers near the patient. Position patients with impaired mobility where they can see out a window or watch local traffic on the unit.
Hearing	Decrease or eliminate distressing auditory stimuli (change bedroom, talk with family members about noise of stereos and other such equipment, use earplugs, use headphones to listen to soft music). Develop a sensitivity to different sounds (music, chirping birds, night sounds, different voices). Use the telephone to maintain contact with family and friends. Use television, radio, CDs to keep current and to stimulate mental activities. Recall favorite sounds of the past with the situations in which they were heard.	Speak in a warm and pleasant tone and communicate caring to the patient. Use your voice to orient the patient to the environment and current situation (e.g., procedure, treatment). Avoid speaking about the patient to others within the patient's hearing. Remember that patients overhearing snatches of conversation outside their room often presume it is about *them!* Decrease extraneous noise (intercom, movement of carts, loud conversations of staff); use carpets and sound-absorbing material whenever possible.
Taste	Experiment with foods of different tastes (seasonings), colors, temperature, and textures; realize that as taste buds age, things will no longer taste the same. Practice thorough oral hygiene and have regular dental examinations. Recall foods that tasted especially good in the past and the events surrounding these tastes (e.g., grandparent baking cookies or homemade bread).	Consult with the dietitian about preparing meals with varied taste sensations; serve meals attractively. Perform routine oral hygiene for patients who are unable to do this for themselves.
Smell	Consciously savor smells that are pleasant; decrease or eliminate noxious odors. Recall pleasant aromas or smells from the past and the events surrounding them (e.g., smell of the ocean when nearing the vacation house, smell of fresh pine in the house at Christmas, the body scent of a loved person or animal).	Keep the patient's room well ventilated, using opportunities when the patient is out of the room to air it out. Remove dressings, drainage, and any equipment with odors from the patient's room as quickly as possible. Encourage patients to focus on pleasant or familiar smells, such as coffee, newspaper, or flowers. Avoid wearing heavy perfumes.
Touch	Consciously surround yourself with different textures and let yourself feel and enjoy them	Include different textures in the patient's environment (silky pillow sham from

(scratchy afghan; a puppy's moist, wet tongue; soft petal of a flower; smooth silk scarf; mug of hot chocolate).
Allow these textures to evoke memories of past tactile experiences (grandchild's hug may bring back memories of hugs from own children, scrap of fabric may recall a prom dress or wedding gown or baby blanket).
Recognize the need to be touched and tell someone, "I need a hug today!"
Receive tactile stimulation from a pet.

home, soft sheepskin, wooly blanket).
Respect the patient's need and desire to be touched or not touched (touch the patient's forearm or shoulder, hug the patient).
Use physical care (bath time, foot soaks, hair care, back massages, turning and positioning, passive range of motion) to provide tactile stimulation.
Limit intrusive procedures and times when the patient needs to be uncomfortably manipulated.

PROMOTING HEALTH LITERACY

Risk factors for inadequate health literacy include advanced age, low educational level, poverty, inability to read, learning disabilities, and lack of English proficiency. Patients may also be at risk for inadequate health literacy because of hearing or visual impairments or confusion and inability to process or remember what is heard. See the Promoting Health Literacy box for ideas on how to help a patient with a hearing deficit. You can also download The Joint Commission white paper, "What Did the Doctor Say?": Improving Health Literacy to Protect Patient Safety, at https://www.jointcommission.org/assets/1/18/improving_health_literacy.pdf

Promoting Health Literacy

IN PATIENTS WITH HEARING DEFICITS

Patient Scenario

Patient Scenario

Mr. Rosato is 84 years old, and until recently had no difficulty hearing. He lives in a long-term care facility because of complications from several serious diseases: diabetes, congestive heart failure, high blood pressure, and degenerative joint disease. His daughter, who visits frequently, informs you, the nurse manager, that Mr. Rosato seems to be having increasing difficulty with hearing, although he denies this. She shares that he sometimes answers questions inappropriately or asks people to speak louder, and she noticed that his television volume is always loud. She made an appointment for him with an audiologist but shares that she does not know the first thing about hearing disorders.

Nursing Considerations: *Tips for Improving Health Literacy*

Compliment the daughter's keen observation, report that sensory disorders are common among older adults, and tell her how important the visit with the audiologist is. Give her an information sheet about hearing disorders and tips on finding out more information about the disorder online from a credible source. Encourage her to be prepared to ask the audiologist three questions:

- What is her father's main problem?
- What do they need to do?
- Why is it important for them to do this?

What additional measures can you take to help increase health literacy in this patient and his family? What other measures would be helpful if Mr. Rosato or his daughter does not speak English, cannot read, or has other learning deficits?

MEETING THE NEEDS OF PATIENTS WITH REDUCED VISION

Always check with the health care provider to learn whether a patient's visual problem is temporary, permanent, partial, or complete, and the degree to which the problem is likely to affect the patient's everyday functioning. This information is vital to developing a realistic teaching plan or care plan.

The first priority is to teach patients self-care behaviors for maintaining vision and preventing blindness, such as the following:

- Know that regular exercise maintains blood flow to the eyes.
- Plentiful sleep keeps eyes lubricated and helps remove irritants.
- Do not rub the eyes.
- Avoid eyestrain (e.g., reading in poor light or viewing television or smart devices when tired).

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Avoid damage from ultraviolet rays.
- Protect eyes from foreign bodies.
- Keep eyeglasses clean, protected, and adjusted.
- Do not use nonprescription eye drops, and seek attention for symptoms.
- Do not clean eyes or contact lenses with soiled articles.
- Use caution with aerosol sprays.
- Use caution with ammonia, lye, and other chemical agents.
- Visit your health care provider frequently if you are prone to eye problems.
- Know the danger signals that indicate serious eye problems, including persistent eye redness; pain or discomfort, especially after injury; visual disturbances; crossing eyes; a growth on or near the eyes; discharge or increased tearing; and pupil irregularities.

When communicating with patients with reduced vision, follow these guidelines:

- Acknowledge your presence in the patient's room. Identify yourself by name.
- Speak in a normal tone of voice. Remember that the blind person is unable to pick up most nonverbal cues during communication.
- Explain the reason for touching the person before doing so.
- Keep the call light or bell within easy reach of the person and place the bed in the lowest position.
- Orient the person to sounds in the environment.
- Orient the person to the arrangement of the room and its furnishings. Clear pathways for the person, and do not rearrange furnishings; clarify this policy with housekeeping personnel.
- Assist with ambulation by walking slightly ahead of the person, allowing the person to grasp your arm.
- Stay in the person's field of vision if they have partial or reduced peripheral vision.
- Provide diversions using other senses.
- Indicate to the person when the conversation has ended and when you are leaving the room.

MEETING THE NEEDS OF PATIENTS WITH REDUCED HEARING

Temporary hearing losses are most often conductive in nature, that is, due to a problem with the external or middle ear (wax buildup, foreign-body obstruction, infection). However, sensorineural hearing losses caused by inner ear or central nervous system problems may not be totally correctable. Health teaching to prevent hearing problems includes the following recommendations for patients:

- Watch your weight, blood sugar level, and blood pressure to keep the tiny arteries that fuel hair cells in your ears healthy.
- Avoid excessive noise.
- Do not insert sharp objects into ears.
- Do not clean the ears excessively.
- Avoid practices that can cause infection; treat infection early.
- Use devices or aids to amplify the sound of your TV.
- Know the symptoms of hearing loss: asking others frequently to repeat what they said, an inability to hear at a distance, need to see the person who is talking, leaning forward or turning an ear toward the speaker, answering inappropriately, talking too loudly, inability to carry on a phone conversation, strained facial expression.

When communicating with patients who have hearing deficits or impairments, follow these guidelines:

- Orient the person to your presence before initiating conversation, such as by moving so you can be seen or by gently touching the person.
- Decrease background noises (television, radio), if possible, before you speak.
- Make sure that the patient's hearing aids (if applicable) are working optimally.
- Position yourself so that the light is on your face and the person can see your lips and expressions.
- Talk directly to the person while facing them, or angle your chair so that your voice reaches the ear that hears best. If the person can lip-read, use simple sentences and speak in a quiet, natural manner and pace. Be aware of nonverbal communication.
- Do not chew gum, cover your mouth, or turn away when talking with the person.
- Demonstrate or pantomime ideas you wish to express, as appropriate.
- Use sign language or finger spelling, as appropriate.
- Write any statement that you cannot convey to the person in another manner.

Aids for people with reduced hearing include telecommunication devices (TDDs), infrared systems, computers, voice amplifiers, amplified telephones, low-frequency doorbells and telephone ringers, closed-caption TV decoders,

flashing alarm clocks, and flashing smoke detectors. The Centers for Disease Control and Prevention has numerous resources to prevent hearing loss (search for "hearing loss" at www.cdc.gov).

Dolores Pirolla, the wife of the patient who has a visual deficit and is now demonstrating signs of a hearing deficit. The nurse would incorporate knowledge of the guidelines (for communicating with people with reduced vision and hearing) when developing a teaching plan to assist Mrs. Pirolla in dealing with her husband's condition. In addition, the nurse could enlist the aid of social services to help Mrs. Pirolla obtain supportive services for her husband's visual impairment and obtain assistive devices for her husband to minimize the effects of the hearing deficit.

COMMUNICATING WITH A PATIENT WHO IS CONFUSED

Some patients who lack the mental ability to process environmental stimuli may be aware of this inability and find it frustrating. Such patients need support to make adjustments to this limitation. Other patients in a similar situation may be oblivious to their deficiency. In both instances, always protect the safety of the patient while providing optimal sensory stimulation.

Ori Soltes, the patient in the ICU who becomes confused, most likely is experiencing a high level of frustration. Because of his accident, he suddenly is thrust into an environment filled with unfamiliar sights, sounds, and activities, leading to feelings of being overwhelmed physically and emotionally. His level of frustration may be further increased by his inability to speak while receiving mechanical ventilation.

Nursing interventions for the patient who is confused include the following:

- Use frequent face-to-face contact to maintain the patient's social dimension. Use touch when appropriate (e.g., walk arm in arm, hug, give a back rub).
- Speak calmly, simply, and directly to the patient and allow sufficient time for the patient to think before responding.
- Orient and reorient the patient to the environment, and fill the patient's personal space with as many personal objects as possible.
- Use conversation, watches, clocks, calendar, newspaper, television, radio, and other such devices to help orient the patient to time, place, and person.
- Clearly communicate that the patient is expected to perform all the self-care activities they can.
- Emphasize the patient's strengths rather than deficiencies, and verbally reinforce strengths.
- Offer the patient simple explanations for care, new activities, and so on.
- Vary environmental stimuli gradually while keeping the environment structured enough that the patient feels comfortable and at home.
- Use objects from the patient's past (e.g., a favorite baseball, a picture of a train, a photograph) to spark reminiscences and discussions.
- Reinforce reality if the patient is delusional.

A list of selected cognitive stimulation activities may be found in Chapter 8.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

COMMUNICATING WITH A PATIENT WHO IS UNCONSCIOUS

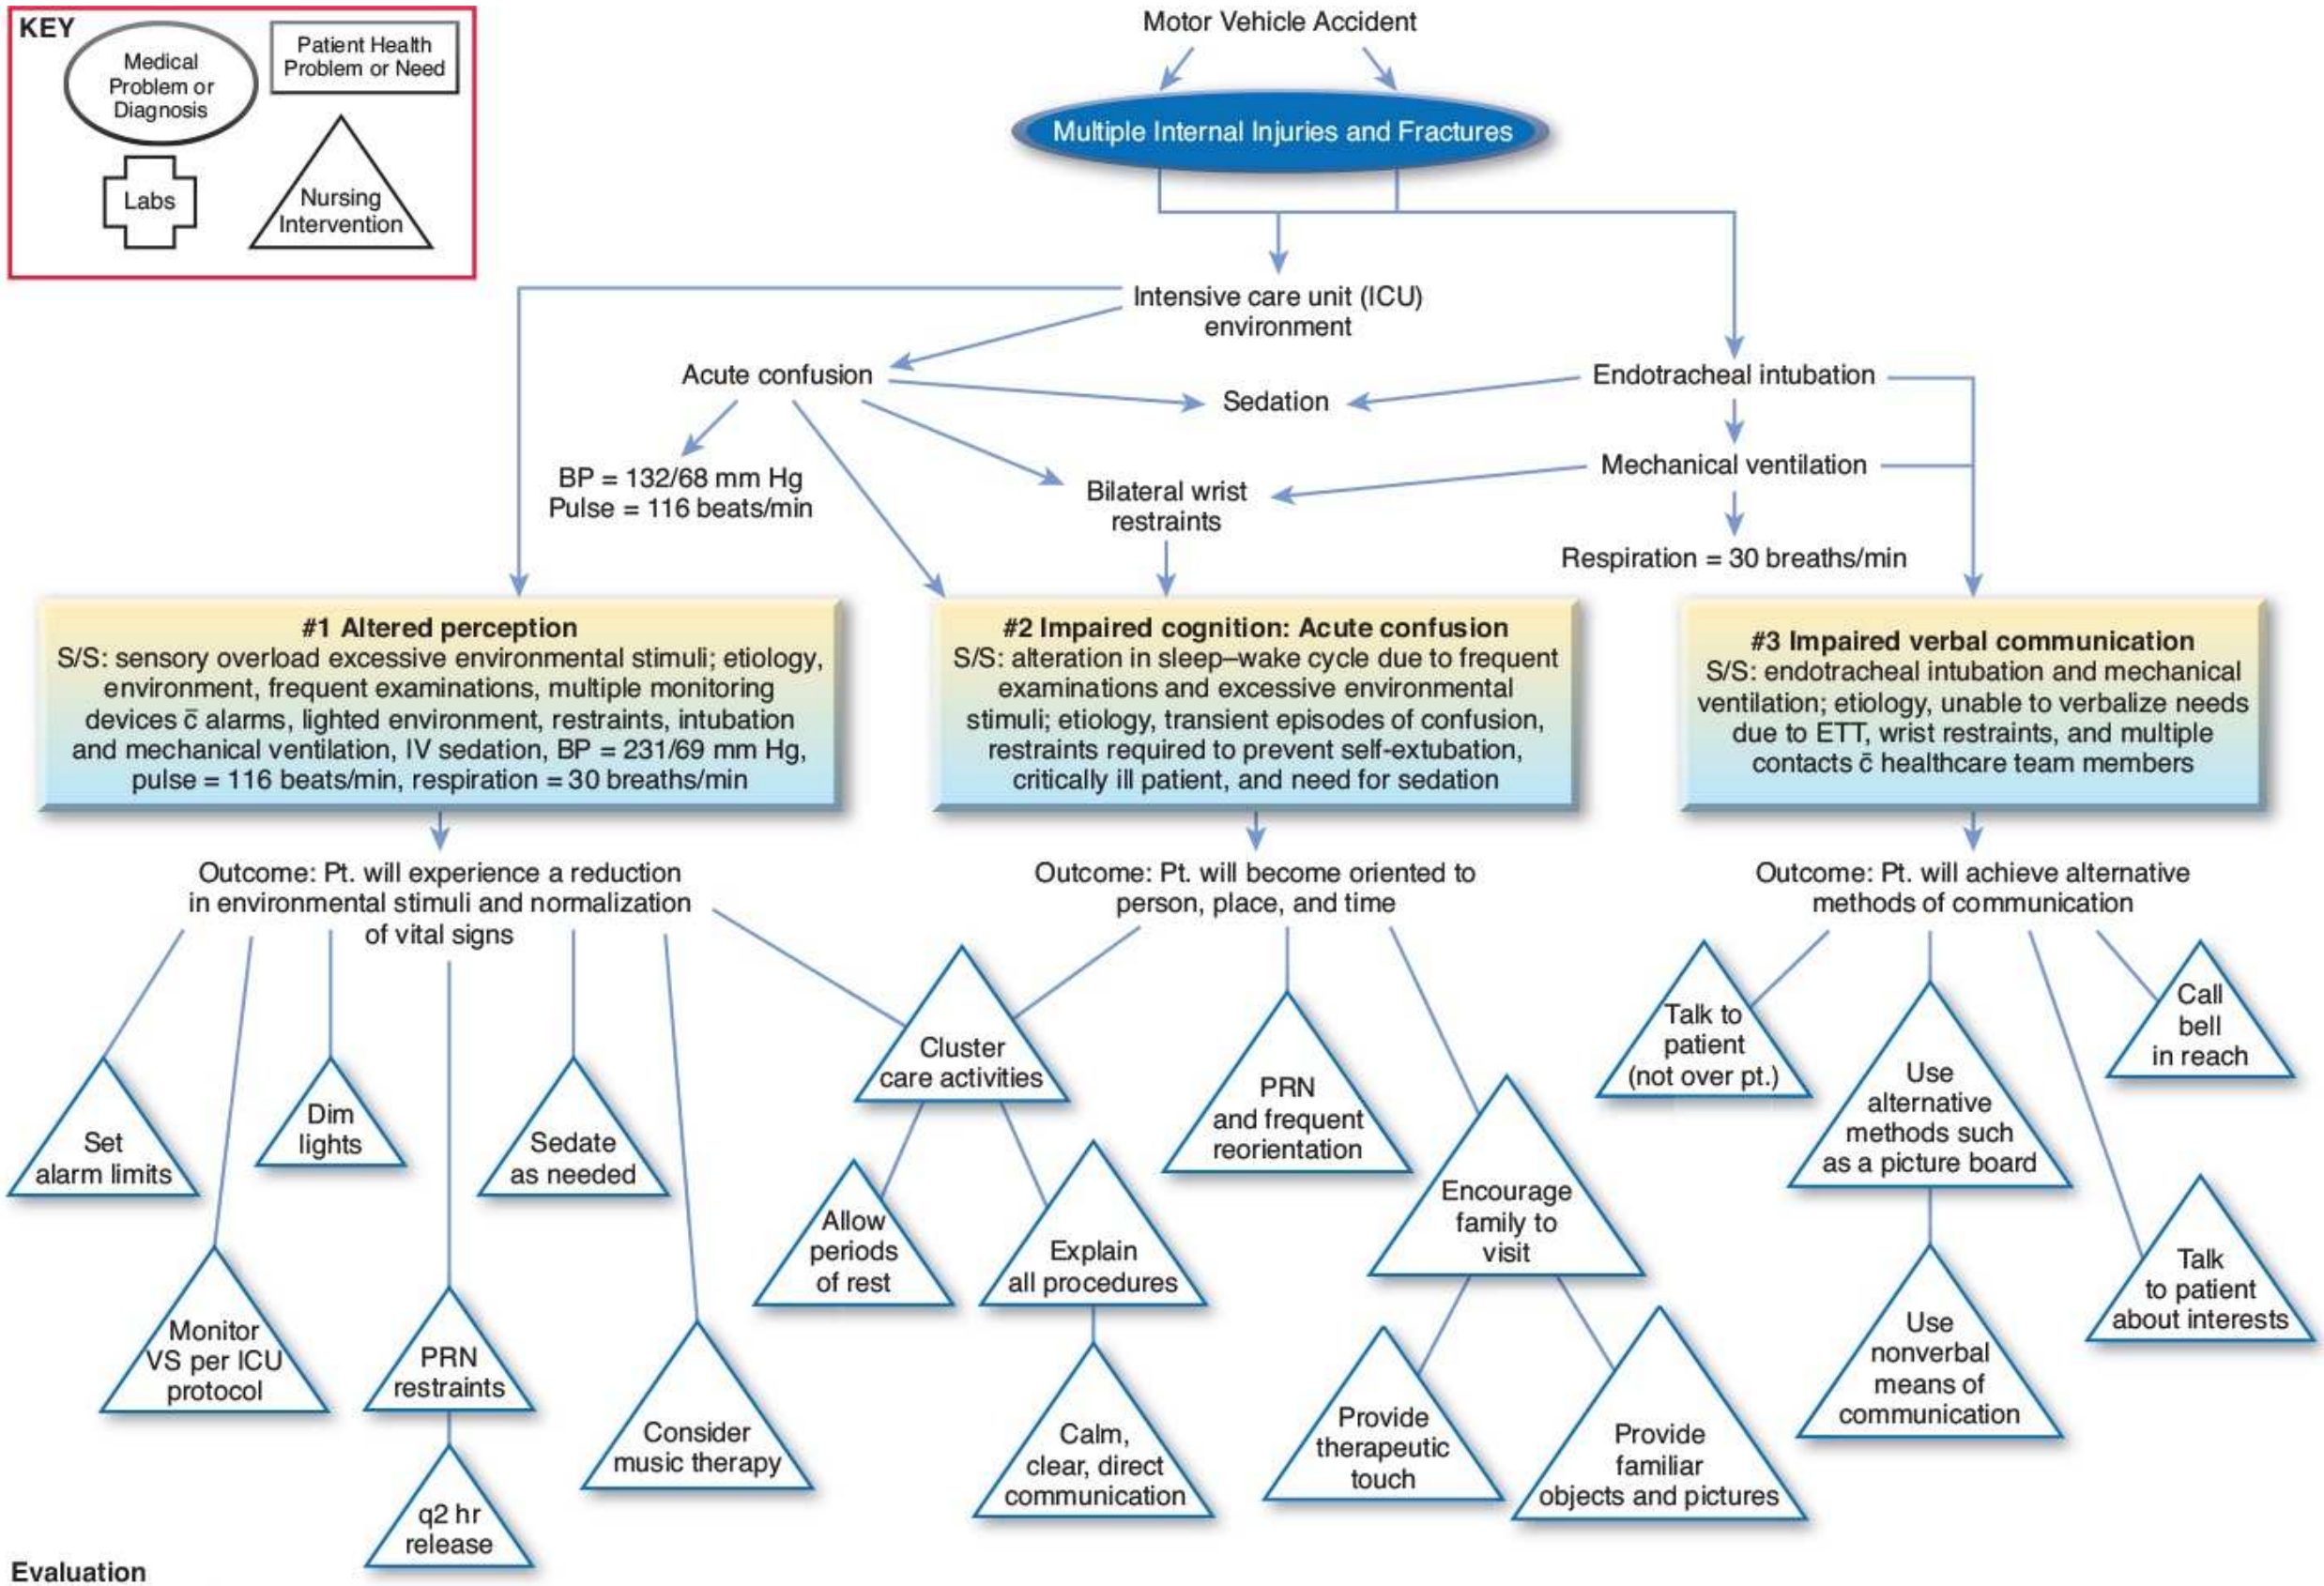
The following are recommended guidelines for communicating with a patient who is unconscious:

- Be careful of what you say in the person's presence. Hearing is believed to be the last sense lost; therefore, the person is often likely to hear what is being said, even if there does not appear to be a response.
- Assume the person can hear you. Talk with the person in a normal tone of voice about things you would ordinarily discuss.
- Speak to the person before touching. Remember that touch can be an effective means of communicating with the unconscious person.
- Keep environmental noises at as low a level as possible. This helps the person focus on the communication.

Evaluating

While implementing a nursing care plan designed to decrease excessive sensory stimuli or increase meaningful stimuli, evaluate the plan's effectiveness by observing for a decrease in the behavioral manifestations of sensory deprivation or overload. You may conclude that the care plan is working if a patient who had begun to withdraw and spend most of the day lying in bed with a blank facial expression appears more alert and begins to initiate conversations and to take an interest in personal care. Also evaluate the patient's ability to interact appropriately with the environment while practicing necessary self-care behaviors, as well as the patient's need for nursing care versus the person's ability to manage the care plan independently.

Ideally, the patient and family learn to manipulate the environment to promote optimal sensory stimulation for growth and development. Patients with specific sensory impairments are evaluated for their knowledge of the impairment, acceptance and management of the treatment regimen, and their ability to perform necessary self-care activities. See the accompanying concept map for Ori Soltes and Evolving Case Study 45-1 for the Pirollas on pages 1854–1855.



REFLECTIVE PRACTICE LEADING TO PERSONAL LEARNING

Remember that the objective of reflective practice is to look at an experience, understand it, and learn from it. As you begin to develop your expertise in identifying and responding to sensory alterations, reflect on your experiences—successes and failures—in order to improve your practice. Are you routinely aware of your patients' environments and the degree to which these stimulate the senses? Have you ever identified sensory deprivation or overload and developed evidence-based strategies to address these problems. Have you encountered patients or their family caregivers whose sensory needs are unmet? Have you created partnerships with family caregivers to identify ways to stimulate senses of at-risk patients? Equally important, do you take mini-breaks and focus on your own experience, savoring the taste and texture of a summer tomato, marveling at the tenacity of a newborn grasping your finger, or quieting to listen to the next crack of thunder during a summer storm?

Perhaps the most important questions to reflect on are: Are your patients and their families/caregivers better for having had *you* share in the critical responsibility of partnering with them to stimulate their senses or improve their alterations in sensory perception? Are your patients now receiving thoughtful, person-centered, prioritized, holistic, evidence-based treatment and care because of your efforts?

EVOLVING CASE STUDY 45-1

Scenario: Dolores Pirolla, a 74-year-old woman, comes to the older adult clinic with her 77-year-old husband, who was diagnosed with macular degeneration and progressive vision loss. She states, "Now I've noticed he's also having difficulty hearing me. I'm worried because he doesn't want to leave the house and we hardly see any of our

Evaluation

- **Diagnosis #1** Ori's environment has been managed to reduce stimuli. Sedation has only been required every 4 hours. Vital signs have returned to normal.
- **Diagnosis #2** Ori continues to exhibit transient periods of confusion but with decreasing frequency. Continue interventions.
- **Diagnosis #3** Ori has been unable to use picture board due to his weakened condition. Continue interventions.

Concept map that displays the use of the nursing process in designing a care plan for Ori Soltes. BP, blood pressure; c̄, with; ETT, endotracheal tube; HCP, health care provider; IV, intravenous; PRN, when necessary (from L. pro re nata); Pt., patient; q2, each/every (from L. *quaque*); S/S, signs and symptoms; VS, vital signs.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

friends anymore. We used to go out to the movies or dinner at least once a week. Lately, if we get out once a month, that's a lot!"

QUESTION r/t CUES: Which assessment should the nurse prioritize in caring for this couple?

A. Vision exam to check for progression in visual defects
B. Vital signs: temperature, pulse, respiration, blood pressure
C. Hearing exam to determine degree of hearing impairment
D. Degree to which sensory deficits are impacting ability to socialize and meet social needs

Scenario: After a brief discussion to establish rapport and flesh out their concerns, the nurse completes the physical assessment and notes that the husband's hearing on the left side is verifiably compromised, although he is not admitting to any difficulties hearing. Dolores is quite vocal about the challenges of now living with her husband who frequently cannot see or hear her, and she is most concerned about his not wanting to admit to any deficits and resulting serious diminishment of time they spent with family and friends.

QUESTION r/t ANALYZING CUES: The nurse is completing documentation in the electronic health record (EHR) on this client. How should the nurse document these findings?

A. Increasing social isolation as a result of increasing sensory impairment
B. Progressive visual and hearing impairment
C. Inability to accept aging and its decline
D. Impaired self-esteem with self-protective behaviors

Scenario: The nurse completes the documentation and says to the husband, "I understand that it is getting harder and harder for you to read and see your surroundings clearly and hear what people are saying, Mr. Pirolla. Frequently when this happens, people tend to isolate themselves so they don't get embarrassed by not hearing a question or answering it incorrectly, or by not seeing something. Do you think this might be happening to you? I know that Mrs. Pirolla is missing the frequency of times you used to meet with family and friends." He slowly nods his head that this is the case.

QUESTION r/t PRIORITIZING HYPOTHESIS: Based on the objective and subjective assessment of this patient, which priority problem should the nurse identify to guide the plan of care?

A. Sensory Deficit: Vision
B. Ineffective Health Maintenance
C. Social Isolation
D. Decreased Self Esteem

Scenario: The nurse opts to explore what visual or hearing aids might be tried to reduce the sensory deficits and to also explore what type of social interactions would be most comfortable for Mr. Pirolla and his wife, together and separately.

QUESTION r/t GENERATING SOLUTIONS: Which interventions will be most effective for addressing the sensory deficits and their impact on social interactions?

A. Making sure that his vision and eye exams are recent and accurately document his sensory deficits
B. Investigating their insurance plan to see what devices they can afford
C. Assessing which auditory and visual aids best improve Mr. Pirolla's sensory and social functioning and that he is willing to try
D. Identifying the family and friends with whom Mr. Pirolla is most comfortable

Scenario: When you next see the Pirollas, you notice that Mr. Pirolla seems more withdrawn—he responds only when pressed and only in one-word answers; he is not holding eye contact but instead looks down at his folded hands in his lap. Mrs. Pirolla remains animated, talks over her husband, and voices her frustration and impatience.

QUESTION r/t TAKING ACTION: Mr. Pirolla does not readily respond to questioning, leaving Mrs. Pirolla to speak for him. While you are trying to engage Mr. Pirolla, Mrs. Pirolla launches a tirade about his "stubbornness" and "insensitivity" to her needs. What is the priority nursing intervention?

A. Counsel both partners that accepting age-related changes can be a huge challenge and not solved quickly.
B. Remind both partners that, as Bette Davis said, "Old age is no place for sissies."
C. Use motivational counseling to try to identify each of their commitments to resolving the challenge of social isolation.
D. Repeat everything you told them before during the previous counseling session.
E. Recommend marriage counseling.

Scenario: Mr. and Mrs. Pirolla reflect on their situation and have articulated potential paths forward. Mrs. Pirolla is no longer visibly upset and is focused on attending to her husband. Mr. Pirolla is still formulating his thoughts

and indicates he will discuss them with his wife at home.

QUESTION r/t EVALUATING OUTCOMES: Which of the following parameters must be in place to ensure a successful resolution of the reason for the Pirolla's initial visit? Select all that apply.

A. Mr. Pirolla is looking into adaptive devices (hearing aid, new glasses) to make socializing more possible for him.
B. Mrs. Pirolla reports that she no longer has to yell to get her husband's attention and that the TV can be kept at a moderate volume.
C. Mr. Pirolla regains 20/20 vision.
D. Mrs. Pirolla reports that her husband seems to be enjoying family visits more and no longer withdraws to his study.
E. Mrs. Pirolla reports that they both seem content with their "new normal" social life.
F. Mrs. Pirolla reports that they have pretty much resumed their active social life.

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

. Work through the Evolving Case Study 45-1, The Pirollas, to help develop your clinical reasoning and clinical judgment skills.
. Describe the practical measures you would take to stimulate the senses of the following sensory-impaired patients. Think carefully about the special sensory needs that accompany different conditions.

- A deaf child
- A confused older adult
- An adult man who has just lost his sight
- A premature infant whose skin is extremely fragile

. Visit a critical care unit with other students and list all the factors that contribute to sensory overload or deprivation. Try to identify how the critical care culture evolved in ways that are actually harmful to patients. Discuss which of these factors are unavoidable and which could be modified to better meet patient needs. Identify individualized nursing strategies to minimize sensory overload and deprivation.
. Dolores Pirolla expresses concern about her husband's safety at home—especially when she is not present—because of his increasingly limited vision. What resources can you recommend to her to "safety proof" their house?
. How do you respond to the following questions?

a. My daughter seems bright enough, but her grades are barely passing. Could it be her eyesight?
b. My mother who lives alone has been complaining of hearing music when there is no source for the music. I'm afraid she may be getting Alzheimer disease.
c. I'm worried I might have COVID-19 because, all of a sudden, I've lost my sense of smell… what do you think?
d. I am really worried about my children spending all their time in front of a screen now that the schools are closed. If it's not their schoolwork, it's their phones. This can't be good for their eyes, can it?

PRACTICING FOR NCLEX

. A nurse in a long-term care facility notes that a patient with limited activity related to severe rheumatoid arthritis is at risk for sensory deprivation. Based on this information, which interventions will the nurse include in the care plan? Select all that apply.

a. Using a lower tone when communicating with the patient
b. Providing interaction with children and pets
c. Decreasing environmental noise
d. Ensuring that the patient shares meals with other patients
e. Discouraging the use of sedatives
f. Providing adequate lighting and clear pathways of clutter

. A nurse in the neonatal intensive care unit (ICU) is planning care to reduce inappropriate sensory stimulation to their patients. Which interventions could the nurse include in the care plan? Select all that apply.

a. Providing bright mobiles and objects for the neonate to look at
b. Rocking the neonate frequently, especially when crying
c. Maintaining reduced ambient light, similar to conditions in the womb
d. Reducing vestibular stimulation, such as rocking
e. Playing music or singing to the neonate to stimulate hearing

. A nurse is assessing a patient for gustatory disturbances. Which question asked by the nurse would be appropriate for this assessment?

a. "Have you been experiencing any loss of taste or strange tastes lately?"

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

b. “Have you smelled odors lately that others cannot smell?”
c. “Can you tell me what object I am placing in your hand right now?”
d. “Have you found it difficult to communicate verbally?”

. A nurse observes that a patient with a history of cataracts is sitting closer to the television than usual. When assessing the patient, which additional findings will the nurse anticipate?
a. Clouding of the lens in one or both eyes
b. Eye pain when performing close work
c. Abrupt loss of vision
d. Loss of central vision

. A nurse supervises APs in a long-term care facility where many residents have presbycusis. What directions will the nurse give the APs to best promote communication with these patients?
a. Provide patients with large-print written menus.
b. Speak clearly and distinctly, using a lower tone of voice.
c. Decrease tactile stimulation.
d. Remind all patients to “call, not fall.”

. A patient is in the late stages of AIDS, which has affected their brain function and memory. The patient reports loneliness because his friends “are afraid to visit.” Based on this data, what nursing intervention would best help meet the patient’s need for sensory stimulation?
a. Providing stimulation through music, television, or movies
b. Assessing the patient’s hearing and vision to ensure optimal function
c. Ensuring the patient is able to transmit their message to others
d. Arranging for a volunteer to sit with the patient each day

. A home care nurse is visiting a group of patients. Which patient does the nurse identify as having the highest risk for sensory deprivation?
a. Older adult confined to bed at home after a stroke
b. Adolescent in an oncology unit working on homework
c. Pregnant patient in active labor
d. Toddler awaiting same-day surgery in a playroom

. A nurse is caring for a patient with a traumatic spinal cord injury that resulted in paraplegia (paralysis) and sensory loss from the waist down. When obtaining data about this patient, what component of sensory function does the nurse plan to assess?
a. Transmission of tactile stimuli
b. Adequate stimulation in the environment
c. Reception of visual and auditory stimuli
d. General orientation and ability to follow commands

. A school nurse is performing vision screenings on middle-school children. The nurse notes a student squinting and that their visual acuity using a Snellen’s eye chart is 20/160. When questioned, the student states their grades have dropped, and they are having difficulty completing work on time. What is the best recommendation for the nurse to make to the student’s guardian(s)?
a. Purchase or prepare a calendar to organize assignments.
b. Ensure the student understands what is expected of them in each class.
c. Seek medical attention if the student has eye pain while at home.
d. Obtain an appointment with an eye professional for further evaluation.

. A nurse is caring for a patient with a severe hearing deficit who reads lips and uses sign language. Which nursing intervention would best prevent sensory alterations for this patient?
a. Turning the radio or television volume up very loud and closing the door to his room
b. Preventing embarrassment and emotional discomfort as much as possible
c. Providing daily opportunities for them to participate in a social hour with six to eight people
d. Encouraging daily participation in exercise and physical activity

. In a group home where most residents have varying degrees of visual or hearing impairments and some are periodically confused, what nursing action is essential?
a. Maintaining safety and preventing sensory deterioration
b. Insisting that residents participate in as many self-care activities as possible
c. Emphasizing and reinforcing individual patient strengths

d. Encouraging reminiscence and life review in groups

. A visiting nurse conducts a visit for an 11-month-old infant. The nurse finds the infant lying on the floor, rocking back and forth with a flat expression, and few vocalizations. Which nursing action would be appropriate at this time? Electronic Health Record 1/2/2025, 1000, Nurses note, age 8 months: infant not vocalizing or babbling; parents admit they do not know how to provide stimulation to the infant. The infant is cared for during working hours by the grandmother who has reduced vision. Parenting classes recommended to help promote sensory stimulation. S. Smith, RN 4/2/2025, 1300, Nurses note, age 11 months (follow-up visit): parents stated they attended parenting classes and that they provide sensory stimulation after work, as taught in the parenting classes. The infant is still cared for by the grandmother during working hours. S. Smith, RN

a. Assessing the type of stimulation the infant has been receiving
b. Removing the infant from the grandmother's care as the child has not progressed.
c. Explaining that their negligence has resulted in the child's speech delays
d. Taking no action, as this is expected behavior for an 11-month-old infant

. A nurse is providing information on smoking cessation at a hospital health fair. The nurse teaches that smoking cessation may help prevent what problem?

a. Reduced vision due to macular degeneration
b. Glare from cataracts
c. Presbyopia and the need for corrective lenses
d. Reduced auditory senses

. A nurse is caring for an older adult who has a severe visual deficit related to glaucoma. Which nursing action is most appropriate when providing care for this patient?

a. Assisting the patient to ambulate by walking slightly behind them and grasping the arm
b. Concentrating on the patient's sense of sight and limit diversions that involve other senses
c. Staying outside of the patient's field of vision when performing personal hygiene for them
d. Cueing the patient when the conversation has ended and when leaving the room

. A school nurse is teaching a group of high school students about preventing hearing loss. What preventative actions does the nurse recommend? Select all that apply.

a. Use earphones when listening to music, podcasts, or other programs.
b. Do not insert objects such as cotton-tipped applicators into the ear.
c. Avoid playing contact sports.
d. Use ear protection when performing tasks with loud sounds.
e. It is best to begin screening for hearing loss at age 18 years.

. A home care nurse is visiting an older adult with long-standing diabetes who reports pain and numbness in their feet. What education is most appropriate for this patient?

a. Take acetaminophen or over-the-counter analgesic when pain occurs.
b. Increase intake of foods containing vitamins B_6, B_{12}, and folate.
c. Explain that phantom limb pain can become chronic, but psychosocial support can help.
d. Validate the patient's understanding of foot care for patients with diabetes.

. When caring for an older adult who repeatedly states their food does not taste as good as it used to, a nurse explains that which factors can contribute to loss of taste as patients age? Select all that apply.

a. Decreased sense of smell
b. Presbycusis
c. Medications
d. Diseases
e. Tobacco use
f. Presbyopia

. During shift report, a nurse is told that their patient admitted with an electrolyte imbalance is experiencing delirium. For which finding consistent with delirium will the nurse assess?

a. Statements that they plan to harm themselves or take their own life
b. Chronic memory loss and personality changes
c. Acute confusion, disorientation, restlessness, or agitation
d. Ability to be aroused by extreme and/or repeated stimuli

ANSWERS WITH RATIONALES

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

. **b, d, e.** For a patient who has sensory deprivation, the nurse provides interaction with children and pets, ensures that the patient shares meals with other patients, and discourages the use of sedatives. Using a lower tone (pitch) of voice is appropriate for a patient with a hearing deficit. Decreasing environmental noise helps relieve sensory overload. Providing adequate lighting and removing clutter is an intervention for a vision deficit; additionally, this promotes safety.

. **c, d.** The neonatal ICU may be a source of excess sensory stimulation. It is recommended that medically fragile infants receive limited light (visuals stimuli) to simulate being in the womb as well as reduced vestibular stimulation. The nurse avoids activities that promote stimulation in this population including soothing, holding, rocking, and changes of position (tactile and kinesthetic sensations), singing and speaking to the neonate (auditory sensations), and changing patterns of light and shade, such as through the use of mobiles and bright objects (visual sensations).

. **a.** When the nurse asks: "Have you been experiencing any strange tastes lately?" the nurse is assessing for gustatory disturbances. The question: "Have you smelled odors lately that others cannot smell?" assesses for olfactory disturbances. When the nurse asks: "Can you tell me what I am placing in your hand right now?" the nurse is assessing for tactile disturbances. The question "Have you found it difficult to communicate verbally?" assesses for transmission–perception–reaction.

. **a.** Cataracts, clouding of the crystalline lens, cause altered sensory reception by interfering with the patient's ability to receive visual stimuli. The other options are not characteristic of cataracts.

. **b.** Presbycusis is an expected decrease or loss of hearing as a result of the aging process. Speaking distinctly in lower frequencies is indicated. Obtaining large-print written material is appropriate for visual alterations. Decreasing tactile stimulation is appropriate for a patient with a sensory overload, and initiating a safety program to prevent falls is appropriate for a patient experiencing kinesthetic/visceral alterations.

. **d.** This patient is receiving decreased environmental stimuli (e.g., from lack of visitors) and may experience problems with reception because of brain involvement. The other options do not alleviate the sensory deprivation of loneliness and isolation.

. **a.** The patient confined to bed rest at home has a high risk for greatly reduced environmental stimuli. The other patients are in environments in which environmental stimuli are present.

. **a.** Trauma to the spinal cord can cause both motor and sensory loss, interfering with transmission of tactile stimuli. Although the other options may be assessed, they do not relate to the spinal cord injury.

. **d.** Visual acuity of 20/160 indicates myopia; this student sees at 20 feet what a person with normal vision can see at 160 feet. The impaired vision is interfering with their academic performance, and further assessment by an eye care professional is indicated. Corrective lenses or a prescription change may be needed. Eye pain is not a symptom of myopia. Although the other options may represent appropriate interventions, they do not flow from the data presented.

. **c.** Providing opportunities for the patient to socialize builds on their strength of being able to lip-read and helps prevent sensory deprivation from hearing loss. Although all the options may be appropriate, they do not address improving sensory deprivation from hearing loss.

. **a.** Safety is a basic physiologic need that must be met before higher-level needs—such as love and belonging, self-esteem, and self-actualization—can be met.

. **a.** Using the first step of the nursing process, assessment, the nurse determines if the types of stimulation given by the infant's parents validate that they understand the education provided at the parenting classes. The grandmother's reduced vision would not impact the child's speech. While the infant's development is not progressing, accusing the parents of negligence is premature; further evaluation by a health care provider may be indicated. It is not the nurse's role to remove a child from a family's care.

. **a.** Macular degeneration is the leading cause of blindness in older adults. Glare from cataracts is an expected symptom, not caused by smoking. There is no indication that smoking is related to the other options.

. **d.** When caring for a patient who has a visual deficit, the nurse should indicate when the conversation is over and when they are leaving the room. When assisting with ambulation, the nurse should walk slightly ahead of (rather than behind) the patient and allow them to grasp the nurse's arm. The nurse should provide, rather than limit, diversions using other senses, and remain in the person's field of vision if partial or reduced peripheral vision is present.

. **b, d.** To prevent hearing loss, the nurse teaches students to avoid concentrating sound in the ear canal, such as when using earphones. In addition, they should not insert objects such as cotton-tipped applicators into the ear canal. For occupations or activities with load sounds, ear protection should be worn. Contact sports are not typically associated with hearing loss. Screening for hearing loss should be performed annually in school-age children.

. **d.** Patients with diabetes can develop peripheral neuropathy resulting in loss of sensation and reduced blood flow. The loss of sensation can promote injury the patient does not readily notice. Therefore, those with diabetes must perform special foot care and visual inspection. The nurse does not prescribe analgesics (medications). Vitamins are indicated when the underlying cause of numbness is identified as a vitamin deficiency. While a decrease in gustatory senses is expected in the older adult, it is unrelated to numbness and pain in the feet.

- **a, c, d, e.** As the patient ages, gustatory senses, along with sense of smell, some medications, and smoking can blunt the taste (gustatory sense). Presbycusis refers to the reduced ability to hear, and presbyopia refers to the inability of the lens to accommodate to near (or far) objects.
- **c.** Delirium is a state of acute confusion manifested by disorientation, restlessness, hallucinations, and agitation. Dementia is a chronic progressive illness characterized by difficulties with spatial orientation, memory, language, and changes in personality. Option a describes a patient who has thoughts of suicide, and option d describes a patient who is displaying stupor. A stuporous state indicates the patient can be aroused briefly by extreme and/or repeated stimuli.

Sexuality

Jefferson Smith

Jefferson, a middle-aged man with a history of diabetes and hypertension, is receiving numerous medications as treatment. During a routine visit to his primary care provider, Mr. Smith confides that he has been having problems “in the bedroom.” He reports difficulty attaining and maintaining an erection.

Paul Rojas

Paul, a young adult man who has told the health care team he is gay, was diagnosed with AIDS. He comes to the clinic today for infusion therapy, which usually takes several hours. Mr. Rojas comments to the nurse, “You don’t feel comfortable with me, do you?”

Amy Liu

Amy is a middle-aged woman who had a hysterectomy about a year ago for excessive uterine bleeding due to multiple uterine fibroids. She comes to the clinic for a checkup and begins to cry during the assessment. She says, “I don’t feel like a woman anymore. My husband and I used to have a wonderful sexual relationship, but now I rarely want to have sexual intercourse, and when I do, it hurts. My husband is being so patient, but I don’t know how much longer he’ll put up with me! What’s wrong with

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

me?”

Learning Outcomes

After completing the chapter, you will be able to accomplish the following:

. Describe reproductive anatomy and physiology.
. Describe the sexual response cycle, differentiating individual responses.
. Describe the concepts of sexuality, gender, gender identity, sexual orientation, and sexual health.
. Perform a sexual assessment, using suggested interview questions and appropriate physical assessment skills.
. Describe types of sexual dysfunction and the assessment priorities for each.
. Identify actual and potential health problems with sexuality that may be addressed by independent nursing actions.
. Plan, implement, and evaluate nursing care related to selected identification of problems involving facets of sexuality.
. Assess how your personal beliefs and values about human sexuality affect your ability to deliver competent, compassionate, and respectful care to patients with challenges, differences, or problems with sexuality.
. Describe effective responses to sexual harassment by patients or colleagues.

premenstrual syndrome (PMS)
sexual dysfunction
sexual harassment
sexual health
sexual orientation

sexuality
sexually transmitted infections (STIs)

A critical component of human identity and well-being, **sexuality** encompasses biological sex or sex assigned at birth, sexual activity (including pleasure, intimacy, and reproduction), gender identities and roles, and sexual orientation (World Health Organization [WHO], 2006, 2021). It involves how a person both exhibits and experiences sexuality physically, emotionally, and mentally. Edelman and Kudzma (2022) define sexuality as the "behavioral expression of sexual identity" (p. 161). Sexuality includes learned behaviors that affect how people respond to their own sexuality and how they behave in relationships with others. Cultural, biological, sociopolitical, legal, economic, religious, spiritual, and historical factors influence sexuality (WHO, 2006, 20121). Sexuality can be an integral part of a person's identity and is present in a person's demeanor through actions, communications, and physical appearance (see the Reflective Practice box on page 1862 for an example).

SEXUAL HEALTH

Sexual health represents the integration of the somatic, emotional, intellectual, and social aspects of sexual being, in ways that are positively enriching and that enhance personality, communication, and love. Because our sexuality is so basic to our sense of self, nurses need to value sexuality as a critical element of general health and well-being. The WHO (2021) identifies the following critical elements of positive, holistic sexual health:

- Sexual health is about well-being, not merely the absence of disease.
- Sexual health involves respect, safety, and freedom from discrimination and violence.
- Sexual health depends on the fulfillment of certain human rights.
- Sexual health is relevant throughout the individual's lifespan, not only to those in the reproductive years, but also to both the young and the elderly.
- Sexual health is expressed through diverse sexualities and forms of sexual expression.
- Sexual health is critically influenced by gender norms, roles, expectations, and power dynamics.
- Sexual health needs to be understood within specific social, economic, and political contexts.

Nurses must be skilled in identifying and addressing problems related to sexual self-concept, body image, sexual identity, sexual activity, and sexual discrimination or violence.

Think back to **Amy Liu,** the woman who reported changes in sexual desire and pain with intercourse. As a result of these changes, she reported, "not feeling like a woman anymore." The nurse would interpret her statements as reflecting a change in her self-concept and body image secondary to her sexual health issues.

Sexual identity encompasses a person's self-identity, biological sex, gender identity, gender role behavior or expression, and sexual orientation. Biological sex or the sex assigned/documented at birth, is the term used to denote chromosomal sexual development: male (XY) or female (XX), external and internal genitalia, secondary sex characteristics, and hormonal states.

There are instances of difference in sex/sexual development (DSD) that may result in contradictions among chromosomal sex, gonadal sex, internal organs, and external genital appearance (previously referred to as intersex; Dwyer & Greenspan, 2021). Sex assignment with these infants presents a very difficult decision for parents and the entire interprofessional team. Should the parents make the decision based on advice from the provider, or should the decision be postponed until the child is old enough to participate? Challenges exist with the timing of assigning sex (along with the gender implications), physical changes that occur at puberty, and the potential for gender identity disorder (GID). Each patient with DSD is unique and often benefits from ongoing psychosexual care and support (Babu & Shah, 2021).

QSEN Reflective Practice: Cultivating QSEN Competencies

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

CHALLENGE TO INTERPERSONAL SKILLS

During my clinical experience in the HIV/infectious disease clinic, I met Paul Rojas, a single young adult man who is gay and was diagnosed with AIDS. One day, he came to the clinic for infusion therapy, which usually takes several hours.

I was a 20-year-old, single woman who identifies as heterosexual. I had no personal experience with gay or lesbian friends, or with people who identify as bisexual or use other terms to describe their sexual orientation. I was confused and uncertain about how to respond to Paul. How should I approach him? What would we talk about during these several hours at the clinic? I was sure my instructor thought this would be a "great learning experience," but what was I supposed to learn? Usually quite self-confident, I was confused, uncomfortable, and uncertain as to how to act.

Thinking Outside the Box: Possible Courses of Action

- Hide my discomfort and simply provide the technical nursing care Paul needs; spend as little time as possible in his room.
- Refuse this assignment because I am unsure I can provide the care Paul needs.
- Talk with my instructor or another experienced nurse who I respect about my questions and concerns.
- Share with Paul that this is my first experience working with a gay patient and ask him what I should know; spend extra time getting to know him and his experiences with other health care professionals.

Evaluating a Good Outcome: How Do I Define Success?

- Provide the nursing care he needs in a manner that is respectful.
- Learn from this experience how to be respectful of all patients and to interact in a way that affirms their human dignity.
- Gain knowledge about sexual orientation through this experience.

Personal Learning: Here's to the Future!

I met Paul and did exactly what I didn't want to do: I completed the technical nursing care such as vital signs and intravenous care, and then got out of the room as quickly as possible. It wasn't until almost the end of his treatment that he asked me, "You don't feel comfortable with me, do you?" When I answered truthfully that I was very uncertain how to best interact with him due to my lack of exposure and experience, Paul took the lead and began to share stories about his life. When I look back now and realize I almost allowed my fear to prevent me from providing person-centered care to Paul, I could kick myself. Not all patients are willing or need to talk about their sexuality, but Paul recognized that I was an inexperienced student nurse and took the time to explain that his sexuality was integral to who he was as a person. For Paul, it was important I learn to consider sexuality when providing patient care. He opened the door to new perspectives. I hope I always remember to treat patients how they want to be treated and appreciate when they teach me about themselves and their experiences.

QSEN SELF-REFLECTION ON QUALITY AND SAFETY COMPETENCIES DEVELOPING KNOWLEDGE, SKILLS, AND ATTITUDES FOR CONTINUOUS IMPROVEMENT

Do you agree with the criteria that the student nurse used to evaluate a successful outcome? Why or why not? What *knowledge, skills,* and *attitudes* do you need to develop to continuously improve the quality and safety of care for patients?

Patient-Centered Care: How would you develop a respectful and successful partnership with Paul, given your initial fears? How can you best communicate empathy and respect and use this opportunity to learn about Paul and his experiences? How will this experience affect your ability to consider sexuality when interacting with patients? Explain how the nursing student's truthful response to the patient's question affected the therapeutic relationship.

Teamwork and Collaboration/Quality Improvement: What communication and interpersonal skills do you need to improve to ensure that you function as a member of the patient care team? Who might the student have turned to for help when first acknowledging her discomfort? What does quality care for Paul look like?

Safety/Evidence-Based Practice: What does the evidence point to as best practice for Paul? What safety needs does he have and how can you meet them?

Informatics: Can you identify the essential information that must be available in Paul's electronic record to support safe patient care and coordination of care? Are smart devices available for you to use to learn more about Paul and his experiences? Can you think of other ways to respond to or approach the situation? What else might the nursing student have done to ensure a successful outcome?

Gender is not the same as biological sex or sexual orientation; they are distinct concepts. **Gender identity** is the inner sense a person has of being male, female, or nonbinary, which may be the same as or different from that person's biological sex or sex assigned at birth. **Gender expression** is how a person presents themselves to the world, is often expressed on a continuum, and may or may not correspond to gender identity. **Gender diverse** is a term that represents a wide range of gender identities that may vary from expected developmental norms; it includes nonbinary, genderqueer, and gender fluid identities (American Psychological Association [APA], 2020; Dwyer & Greenspan, 2021). People who experience clinically significant distress or impairment because their biological sex or sex assigned at birth is contrary to their gender identity are diagnosed with **gender dysphoria**, a concept designated in the *Diagnostic and Statistical Manual of Mental Disorders* (*DSM-5*). It is important to note that not all transgender or gender diverse individuals experience gender dysphoria (American Psychiatric Association, 2021). **Cisgender** refers to a gender identity or role performance that matches society's expectations based on biological sex. For example, a woman who identifies as cisgender would have a vagina and clitoris (biologically female) and would identify as female (gender).

Transgender, frequently shortened to *trans*, is a term that describes a wide range of experiences or identities where gender identification and expression differ from societal expectations that are based on a person's biological sex. For example, a person born biologically male (penis and scrotum) may identify as female (gender). More specifically, transgender is an inclusive term used to describe those who feel that the sex that was assigned to them at birth incompletely describes or fails to describe them at all. This term includes:

- People who have a gender expression that differs from their biological sex or sex assigned at birth (according to societal norms)
- People who have DSD where their reproductive or sexual anatomy does not fit the typical definition of male or female
- People who identify outside the female/male binary
- People who identify as having no gender or multiple genders

For many transgender people, the solution is to change their bodies, through surgery, hormone therapy, or both, to match their inner feelings; this process is referred to as *transitioning*. The surgery is frequently referred to as *gender affirmation surgery* or *gender confirmation surgery*. The terminology used for the surgery is significant because it reinforces the belief that the surgery is realigning a person with their actual gender.

Teens who are transgender face the reality of puberty, where their body will go through biological changes that betray who they feel they are or who they want to be. Puberty blockers, medications that pause puberty, may be taken to block secondary sex characteristics for a few years. They are generally safe, and their effects are reversible. Exogenous hormones (testosterone or estrogen) may also be administered. When the teen reaches the age of consent and has solidified their gender identification, surgery may be a viable, even medically necessary option (WPATH, 2016). Typically, genital surgery requires two mental health evaluations to confirm gender dysphoria, capacity for informed consent, 12 continuous months of hormone use, control of significant medical or mental health concerns, and living in the gender to which a person is transitioning (WPATH, 2012).

Gender binary (male or female identification) is not the only option. *Gender fluid* describes a person whose gender identification and behaviors shift from time to time, whether within or outside of societal, gender-based expectations. There is an emerging understanding that external genitalia do not always dictate gender identification or gender expression. Some people identify as nonbinary and may prefer the gender-neutral pronouns *they* and *their* rather than *him/her* or *his/her*. For inclusivity and to promote bias-free language in published works, the American Psychological Association (2020) now integrates gender-neutral language into their format and style guidelines (which is reflected in this textbook). Each person's experience is individual, and the vocabulary and terms continue to evolve. There is a growing understanding that asking people their pronouns is appropriate, but a nuanced approach is helpful to maintain rapport in the healthcare environment (Das, 2021). For a current glossary, check out the University of California—Davis Lesbian, Gay, Bisexual, Transgender, Queer, Intersex, Asexual (LGBTQIA) Resource Center at https://lgbtqia.ucdavis.edu/educated/glossary.html.

People experience sexual satisfaction in many ways; what is considered normal differs from one person to another and among cultures. **Sexual orientation** refers to romantic, emotional, affectionate, or sexual attraction to other people (Regents of the University of California, Davis campus, 2020). In general, gender identity is one's psychological self-identification, whereas sexual orientation is who one is attracted to physically, emotionally, and/or romantically. The origins of sexual orientation are unknown, but many studies claim a genetic basis. Some sexual preferences are culturally determined or may be dictated by opportunity.

Although there is possible fluidity and ongoing debate regarding the human sexuality spectrum, commonly identified sexual orientations are as follows:

- **Heterosexual** or *straight* refers to a person who is attracted to a person of the opposite gender.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- **Gay** (males or females) or **lesbian** (females) refers to a person attracted to members of the same gender. (Note that the term *homosexual* is outdated and no longer considered appropriate [GLAAD, n.d.].)
- **Bisexual** refers to a person who is attracted to both males and females. A bisexual relationship or encounter does not necessarily mean a person is gay.
- *Asexual* refers to a person who lacks romantic or sexual attraction to others.
- *Questioning* refers to a person who is unsure of their sexual orientation.

GLAAD's Accelerating Acceptance 2021 survey of more than 2,517 adults provides insight into some trends. Non-LGBTQ Americans recognize that gender is not limited to female and male; the vast majority polled (81%) identified that transgender and nonbinary identities will become an even more familiar part of life, similar to gay and lesbian orientations. Reports of discrimination against LGBTQ persons have increased since 2020, with 6 in 10 LGBTQ people (59%) reporting discrimination based on their sexual orientation and/or gender identity (GLAAD, 2021). Education of children in the history of LGBTQ individuals remains a point of discomfort with non-LGBTQ people. Cultural and sociopolitical trends will continue to impact on the acceptance of the LGBTQ community (GLAAD, 2021).

Consider **Paul Rojas,** the patient with AIDS, who is gay. The nurse would need to also consider his gender identity and gender role behaviors to gain a fuller understanding of his sexual identity and to provide appropriate care.

SEXUAL EXPRESSION

The methods by which people gain satisfaction through sexual stimulation are varied. Touches, smells, sights, sounds, feelings, thoughts, and fantasies can all contribute to sexual fulfillment in any form of expression chosen by people. Feelings of love for another person are closely associated with desire (Fig. 46-1).

Forms of sexual stimulation include kissing, hugging, stroking, squeezing, breast stimulation, manual stimulation of the genitals, oral–genital stimulation, and anal stimulation. Sexual stimulation may be physical or psychological. Erotic stimulation through the use of films, magazines, and photographs is common. Fetishism, more often practiced by males, is sexual arousal with the aid of an inanimate object not generally associated with sexual activity. Items such as shoes, leather, rubber, and women's undergarments might be used.

On a continuum, sexual behavior ranges from adaptive to maladaptive. Adaptive responses meet the following criteria:

- Between two consenting adults
- Mutually satisfying to both
- Not psychologically or physically harmful to either
- Lacking in force or coercion
- Conducted in private

Maladaptive sexual responses are behaviors that do not meet one or more of the criteria for adaptive responses (Boyd & Luebbert, 2022; Stuart, 2013).

A B C D E

FIGURE 46-1. Gender identity, biological sex or sex assigned at birth, and sexual preference may vary, but here are just a few examples of self-identified couples. (*Source:* Used with permission from Shutterstock. *Photos by Hogan Imaging* [**A**], *CREATISTA* [**B**, **C**], and *Monsterstock* [**D**]. **E** courtesy of Paul Harwerth.)

Masturbation

Masturbation is a technique of sexual expression in which a person practices self-stimulation. It is a way for people to learn what they prefer during stimulation and what feels good. Males masturbate by holding and stroking the shaft of the penis. Females find manual stimulation of the clitoris enjoyable, although variations of technique are numerous. Many myths and misinformation surround masturbation. The reality is that people masturbate regardless of sex, gender, age, or marital status. People might not masturbate if they feel guilty about it or believe self-stimulation is wrong. Masturbation is not dirty and will not lead to blindness or insanity.

Sexual Intercourse

The act of **intercourse** (coitus or copulation) is the insertion of the penis into the partner's vagina, anus, or mouth. It usually begins by stimulation of the senses in some way, followed by a period of activity known as foreplay. *Petting* is part of foreplay; it can involve simple stroking of the breasts, arms, back, and neck without genital involvement or may lead to mutual masturbation and orgasm.

Vaginal Intercourse

The act of placing the penis in the vagina, penile–vaginal intercourse, can be accomplished in various positions. The most common position in Western cultures is the *missionary position*, in which the female lies horizontally underneath the male. You may find it interesting that the Polynesians named this position because it was the preferred position for intercourse used by religious missionaries. Couples may find other positions to be more stimulating and comfortable. Clitoral stimulation is difficult to achieve in the missionary position. Lying side by side, female on top, and rear entry are some examples of coital positions that enable clitoral stimulation. Sexually inhibited people may believe they need permission to engage in alternative sexual positions.

When the penis is pushed into the vagina, the male begins rhythmic thrusting movements of the hips to move the penis back and forth along the vaginal walls. The female may match their partner's hip movements with movements of their own body. These movements continue until orgasm is attained by one person or both. Similar vaginal stimulation for the female can be performed with fingers or a synthetic sex toy.

Simultaneous orgasms, or both people attaining orgasm at the same moment, are difficult to achieve. A preoccupation with attaining simultaneous orgasms might disrupt the ultimate intimacy and satisfaction possible during coitus.

The period after coitus is just as significant as the events leading up to it. Caressing, hugging, and kissing deepen the couple's intimacy and should be nurtured, not rushed.

Anal Intercourse

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Anal intercourse, the act of inserting the penis into the anus and rectum of a partner, is another form of intercourse. Commonly practiced by gay men, it is also used by lesbians and heterosexual couples. Once the penis (or any object) is placed in the rectum, it should not be introduced into the vagina without thorough cleansing because many microorganisms present in the rectum can cause vaginal infections. Care should be used to avoid injury to the delicate rectal mucosa, and lubrication is essential for comfort.

Condoms are now recommended for both vaginal and anal intercourse to prevent sexually transmitted infections (STIs).

Oral–Genital Stimulation

Stimulation of the genitals by the mouth and tongue might be used during foreplay or as a way to reach orgasm. Cunnilingus is stimulation of the female genitals by licking and sucking the clitoris and surrounding structures. Fellatio is stimulation of the male genitals by licking and sucking the penis and surrounding structures. One partner or both may use these techniques simultaneously (commonly known as *69* or *sixty-nine*). Some people may use oral–genital stimulation as a replacement for vaginal intercourse to avoid pregnancy.

Abstinence

Abstinence is not having sex. It is the most effective form of birth control, preventing pregnancy 100% of the time when practiced consistently. Abstinence also prevents the transmission of STIs 100% of the time when practiced appropriately and consistently (Centers for Disease Control and Prevention [CDC], 2021a). Some STIs spread through oral–genital sex, anal sex, or even intimate skin-to-skin contact without actual penetration (genital warts and herpes can be spread this way). Therefore, only avoiding all types of intimate genital contact can prevent these STIs. Avoiding all types of intimate genital contact—including anal and oral sex—is complete abstinence. There are no side effects or health risks related to abstinence.

Alternative Forms of Sexual Expression

Alternative forms of sexual expression include the following:

- *Voyeurism*: the achievement of sexual arousal by looking at the body of someone other than one's sexual partner. Although voyeurism itself is not inherently wrong, some voyeurs develop complex means to spy on others that involve violations of privacy that are illegal.
- *Sadism*: the practice of gaining sexual pleasure while inflicting abuse on another person.
- *Masochism*: gaining sexual pleasure from the humiliation of being abused.
- *Sadomasochism*: practicing sadism and masochism together. It might involve being tied up, biting, hitting, spanking, whipping, pinching, and other activities.
- *Pedophilia*: the practice of adults gaining sexual fulfillment by performing sexual acts with children. Unlike the other items on this list that (depending on the circumstances) may be considered adaptive sexual responses, pedophilia involves children who, by nature of their age and maturity, cannot consent to sexual activity. Pedophilia is wrong, illegal, and maladaptive in all cases.

FACTORS AFFECTING SEXUALITY

Many factors influence a person's sexuality and contribute to personal feelings regarding sexuality. The brain, rather than the genitals, plays the most significant role in how people perceive themselves as sexual beings.

Developmental Considerations

The process of human development affects the psychosocial, emotional, and biological aspects of life, which in turn affect a person's sexuality. Biological sex is the only distinguishing trait present at conception. From birth onward, biological sex and gender influence behavior throughout life. Table 46-1 summarizes sexuality throughout the lifespan and the nursing implications for each stage. Individuals with intellectual and developmental disabilities (IDDs) may require additional, individualized support and counseling regarding contraception, preconception planning, pregnancy, and sex education to ensure respect and protection of their autonomy (American Nurses Association [ANA] Ethics Advisory Board, 2020). Although those with IDD report similar rates of sexual activity as those without IDD, they often receive limited education on sex, reproductive health, and methods to prevent pregnancy and STIs. Females with IDD are at greater risk for sexual abuse and benefit from critical education (CDC, 2020b). Always involve the patient in their care and consider any privacy, confidentiality, and informed consent implications.

Culture

The manner in which a society perceives sexuality influences the person. Every culture has its own norms regarding sexual identity and behavior. To some degree, culture dictates the choice of sexual partner, duration of sexual intercourse, methods of sexual stimulation, and sexual positions. In some cultures, women may be expected to merely tolerate sex; in others, the woman's participation is encouraged. To gain an appreciation for all the ways that culture can

influence sexual expression and health, ask people from different cultures the following questions:

- What type of dress is appropriate for children, men, and women? How is nudity viewed?
- What role behaviors and social responsibilities are expected of men and women?
- Is masturbation acceptable?
- At what age is genital sexual intimacy appropriate? With whom is it appropriate?
- What sexual practices are accepted?
- What are the rules for marriage? Is premarital sex, extramarital sex, or polygamy accepted?

The fact that a practice is common in a culture does not mean that it is healthy or ethical. **Female genital mutilation (FGM)**, for example, includes procedures that intentionally injure or alter the female genital organs for nonmedical reasons. It is a procedure that has no health benefits for girls and women and can cause severe bleeding and problems urinating. Later in life, it can cause cysts, infections, and infertility, as well as complications in childbirth and increased risk of newborn deaths. About 200 million girls and women worldwide, primarily in Africa, the Middle East, and Asia, are currently living with the consequences of FGM. The WHO (2020) writes that:

> "FGM is recognized internationally as a violation of the human rights of girls and women. It reflects deep-rooted inequality between the sexes, and constitutes an extreme form of discrimination against women. It is nearly always carried out on minors and is a violation of the rights of children. The practice also violates a person's rights to health, security, and physical integrity, the right to be free from torture and cruel, inhuman or degrading treatment, and the right to life when the procedure results in death" (para. 3).

There are four major types of FGM:

- *Clitoridectomy:* partial or total removal of the clitoris and, in very rare cases, only the prepuce (the fold of skin surrounding the clitoris)
- *Excision:* partial or total removal of the clitoris and the labia minora, with or without excision of the labia majora
- *Infibulation:* narrowing of the vaginal opening through the creation of a covering seal. The seal is formed by cutting and repositioning the inner, or outer, labia, with or without removal of the clitoris.
- *Other:* all other harmful procedures to the female genitalia for nonmedical purposes—for example, pricking, piercing, incising, scraping, and cauterizing the genital area

Religion

Some people view organized religion as having a generally negative effect on the expression of sexuality. For example, in many religions, the concept of virginity came to be synonymous with purity, and sex became synonymous with sin. In addition, many forms of sexual expression other than male–female coitus are considered unnatural by some religions. As a result of the rigid regulations and negative connotation of sex dictated by some religious groups, a number of sexual dysfunctions can be related to a person's resulting guilt and anxiety. Most major religions are reexamining their teachings on sexuality in response to challenges posed by their members. Organized religions, such as Catholicism, have public figures who are moving toward gender inclusivity by accepting and having frank conversations with and about the LGBT communities (Martin, 2017). Many people have recognized the importance of accurate sex education within the realm of the church and organized religions. There is also a new interest in the spirituality of marriage: churches and organized religions are examining their role in supporting the intimate sexual relationship of married couples.

Ethics

Healthy sexuality depends on freedom from guilt and anxiety. What one person believes is wrong may be perfectly natural and correct to another. Some people may feel that certain forms of sexual expression are bizarre, and the people who participate in them are perverted. If the sexual expression is performed by consenting adults, is not harmful to them, and is practiced in privacy, it should not be considered a deviant behavior. People should personally decide which aspects of sexual expression are comfortable for them. There are times that education and support from a health care professional to engage in a different form of expression may effectively alleviate guilt and enhance sexual satisfaction.

Table 46-1 Developmental Aspects of Sexuality Through the Lifespan

STAGE	CHARACTERISTICS	NURSING IMPLICATIONS AND TEACHING GUIDELINES
Infancy: Birth to 18 months	• Needs affection and tactile stimulation • Males have penile erections, and females have orgasmic potential • Gradually can differentiate self	• Avoid early weaning to prevent oral deprivation. • Encourage parents/caregivers to provide ample physical touch, deprivation of which may cause

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

	from others • Obtains pleasure from touching genitals • Often dressed according to social norms based on biological sex or sex assigned at birth	physical and mental underdevelopment. • Self-manipulation of genitals is normal behavior; avoid denoting this as bad or wrong.
Toddler: Ages 1–3 years	• Establishes control over bowels and bladder • All toddlers enjoy fondling genitals • Able to identify own sex and gender • Develops vocabulary related to anatomy	• Allow toddlers to designate readiness for toilet training. Strict measures may lead to compulsive behaviors later. • Punishment of genital fondling may lead to guilt and shame regarding sexual behavior later in life. • Use proper terms for body parts.
Preschooler: Ages 4–6 years	• Becomes increasingly aware of self • Enjoys exploring body parts of self and playmates • Engages in masturbation • Gender identity is formed	• Parents/caregivers may cause anxiety in the child by intolerance of inconsistency of sex-role behavior. • Negative overreaction by parents to child's masturbating behavior can lead to a belief that the genitals and sex are bad and dirty.
School-age: Ages 6–10 years	• Tendency toward attachment to the parent of the opposite sex (when this fits the family model) • Tendency toward having same-sex friends • Curiosity about sex and sharing of fears • Increasing self-awareness	• Same-sex preference for relationships is not related to heterosexual, lesbian, or gay tendencies. • Give child the information (intercourse, abstinence, STI prevention, pregnancy) in a clear, factual form. May look to peers for information that may be incorrect.
Preadolescence: Ages 10–13 years	• Puberty begins for most adolescents with development of secondary sex characteristics • Menarche takes place • May test behavioral limits	• Information is necessary regarding body changes to alleviate fears. This information should be given to the young person before pubertal changes begin. • Parents/caregivers need to find a satisfactory middle ground for rule setting. Rules that are either too rigid or too lenient can interfere with the development of self-confidence and an internal value system. • Treat body image changes with a positive attitude to prevent poor self-image.
Adolescence: Ages 13–19 years	• Primary and secondary sex characteristics develop • Sexual fantasies are common • Masturbation is common • May begin to partake in sexual activity ranging from light to heavy petting to full genital intercourse	• Parents/caregivers share their beliefs and moral value systems with their children. • Teenagers may share their feelings with parents/caregivers. Not taking them seriously may lead to lack of trust and a communication gap.

	• May experiment with same-sex relationships (even if they don't identify as gay) • At risk for pregnancy and sexually transmitted infections • Gender expression and identification is often solidified during adolescence	• Teens need information regarding contraceptive measures and the potential for contracting sexually transmitted infections. • Review receiving and giving consent prior to engaging in sexual activity.
Young adulthood: Ages 20–35 years	• Premarital sex is common • Knowledge regarding sexual response and activity increases pleasure of relationship • May experiment with various sexual expressions • Develops own value system and respects values of other people • Many couples share financial responsibilities as well as household tasks	• Encourage communication between partners regarding sexual needs and differences. • Reinforce the use of abstinence and contraceptive measures to prevent unwanted pregnancies. • Counsel against promiscuous behavior to guard against sexually transmitted infections and loss of trust of partner. • Daily communication is necessary to vent stresses and work out difficulties.
Adulthood: Ages 35–55 years	• Bodily changes as a result of menopause • Couples focus on quality rather than quantity of sexual experiences • Divorce is common • Grown children begin their own lives and sexual experiences • Sexual satisfaction may actually increase because of loss of fear of pregnancy	• People need positive reinforcement of what is good about themselves and their relationships. • Teach parents/caregivers that empty nest syndrome (feelings of loss caused by children leaving) is common. Accentuate positive aspects of this situation. • Encourage couple to use this period as one of renewal for themselves.
Late adulthood: Ages 55 years and older	• Orgasms may become shorter and less intense in both males and females • Vaginal secretions decrease, and period of resolution in males lengthens • May feel need to conform to stereotypes regarding the aging process, and cease sexual activity • Fear of loss of sexual abilities	• Sexual activity need not be hindered by age. • Teach couples that adaptation to bodily changes is possible with use of comfortable positions for intercourse and increased time for stimulation. • Teach alternatives to coitus, such as caressing, hugging, and stroking, when coitus is impossible because of illness or disability. • Couples who have been consistently sexually active throughout their lives may continue their intimate relationship for as long as they desire.

Lifestyle

Modern lifestyles greatly affect sexuality and its expression. All adults are exposed to stress, and many are under considerable strain to perform and function in the workplace as well as at home. Stressors may be external, such as job and financial demands, or internal, such as a person's competitive nature. Varied responsibilities may place a time constraint on communication between a couple, as well as on the energy level and motivation for sexual satisfaction. Although some couples view sexual activity as a release from the stressors of everyday life, most place nurturing relationships and sexual expression far from the top of the list of things-to-do. It is crucial to a relationship's survival

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

that a couple set aside priority time for their relationship—if not for lovemaking, then for intimate, quiet contact. Lifestyle variables can also influence the sexual expression of adolescents and young adults. Young people who receive accurate, direct information regarding sex and develop associated skills to protect themselves are less likely to engage in sexual behavior that involves multiple partners and increases the risk of STIs, unwanted pregnancy, HIV, and other unintended health outcomes (CDC, 2021a).

Menstruation

Menstruation, often referred to as a *period* or menses, is the normal vaginal bleeding that takes place for 2 to 7 days during the monthly menstrual cycle if pregnancy has not occurred. During the menstrual cycle, the body prepares for the presence of a fertilized ovum; if fertilization does not occur, the body sheds the lining of the uterus during menstruation. Cycles are about 28 days long but may vary from 21 to 40 days. The first menstrual period, called **menarche**, is experienced at about age 12 years, but the age of menarche is particular to the person and may occur anywhere between 8 and 17 years. **Menopause**, the cessation of menstrual activity, occurs between the ages 48 and 55 years. There may be irregular menses over time before menstruation ends (Norris, 2019).

The Menstrual Cycle

The menstrual cycle is controlled by a series of reactions that rely on a complex interaction between the hypothalamic–pituitary axis, the ovaries, and the uterus (Norris, 2019). Two cycles occur simultaneously: one in the ovaries and one in the endometrium of the uterus (Fig. 46-2).

In the ovaries, in a typical 28-day cycle, the phase from day 4 to 14 is called the follicular phase. During this phase, a number of follicles mature, but only one produces a mature ovum. At the same time, in the uterus, the endometrium is becoming thick and velvety in preparation for receiving a fertilized egg. This phase in the uterus is called the proliferation phase. Ovulation generally occurs on day 14 when the mature ovum ruptures from the follicle and the surface of the ovary and is swept into the fallopian tube. If sperm are present, the ovum is fertilized at this time. Some individuals can detect ovulation by the presence of a sharp, cramping pain over the ovulating ovary; this pain is called *mittelschmerz*, or middle pain, because it occurs in the middle of the cycle (Norris, 2019).

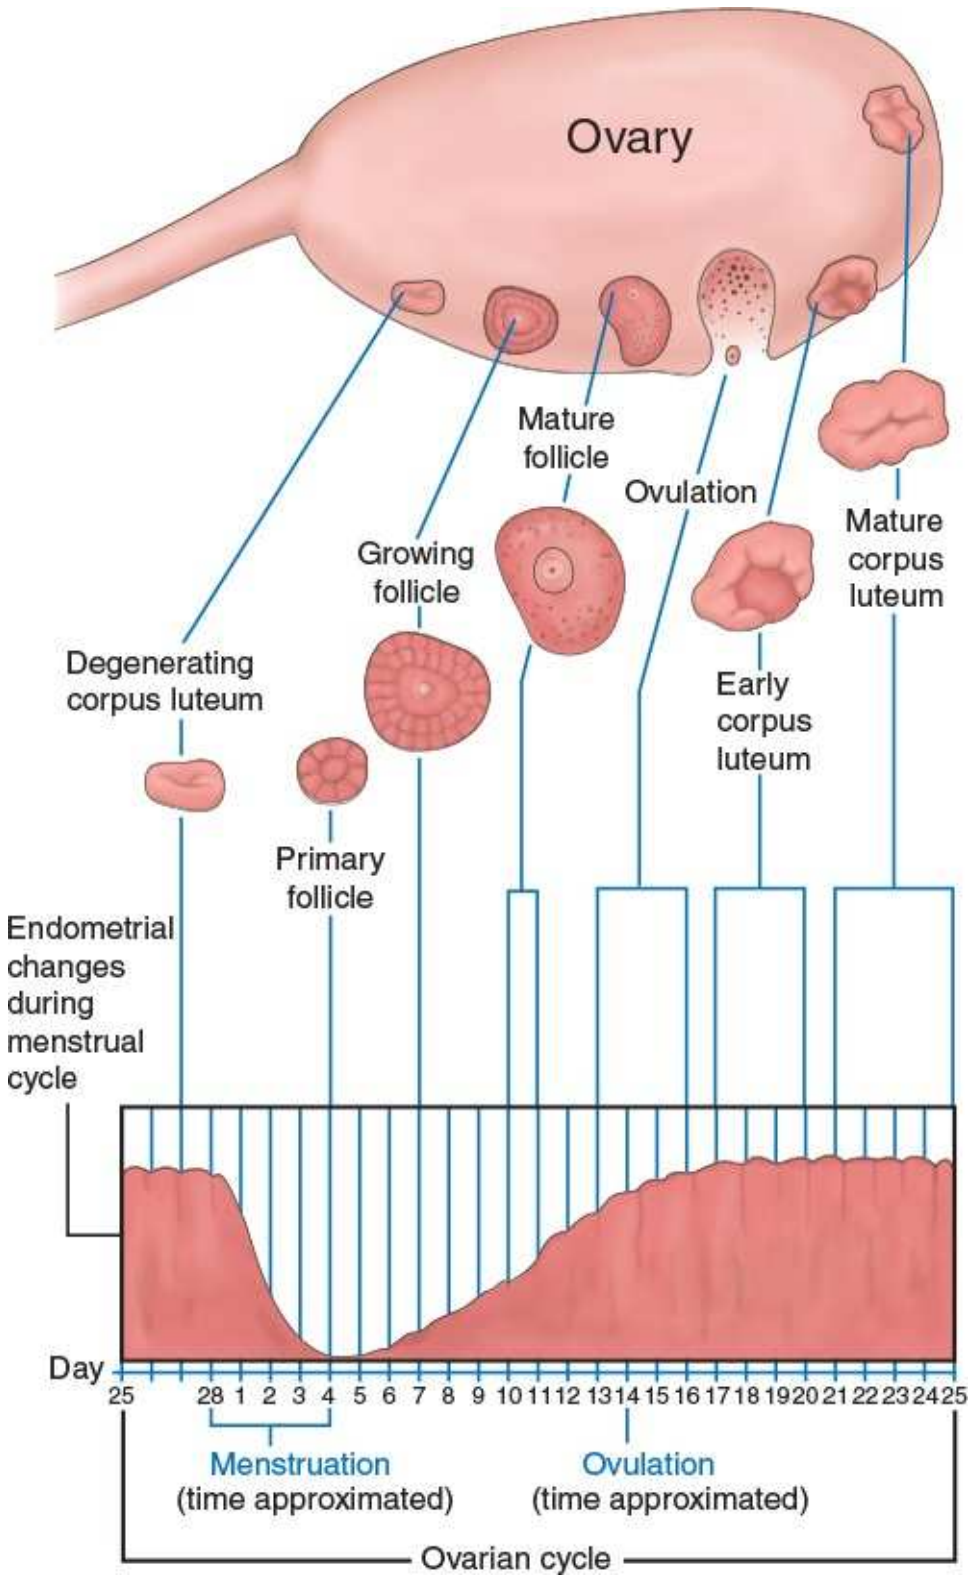

FIGURE 46-2. Schematic representation of one ovarian cycle and the corresponding changes in the endometrium.

From day 15 to day 28, the phase in the ovaries is called the luteal phase. The leftover empty follicle fills up with a yellow pigment and is then called the corpus luteum, or yellow body. The purpose of the corpus luteum is to produce hormones that encourage a fertilized egg to grow. If fertilization does not occur, the corpus luteum begins to disintegrate. During the luteal phase in the ovaries, the uterus also undergoes changes; this phase is called the secretory phase. The endometrial lining thickens. However, in the absence of a fertilized egg, the corpus luteum dies and the endometrial lining disintegrates (Norris, 2019).

At day 28, menses, or the menstrual flow, begins as a result of the uterus shedding the useless portion of its endometrium. Menses lasts for 2 to 7 days (Norris, 2019), with flow averaging 5 days. The menstrual discharge is a bloody fluid that also contains endometrial debris, mucus, and enzymes. Normal blood loss averages 30 to 80 mL. Usually, the flow is the heaviest and is bright red on the first day or two of menses, gradually tapering off to light-brown staining. Many individuals experience some degree of discomfort either premenstrually or during menses.

Menstrual discharge is odorless until exposed to the air, when a person may notice a light, fleshy, pungent odor. Deodorized pads and tampons do little to minimize odor and can cause chemical irritation to the vulva and vagina. Good hygiene and regular bathing are much more effective during menses to prevent odor. Pads and tampons should be changed frequently to prevent odor and irritation from wetness. Individuals using tampons should read and follow the manufacturer's suggestions to reduce the risk for toxic shock syndrome (TSS).

Menstrual cycle irregularities can have many different causes, including the following (Mayo Clinic Staff, 2021; Norris, 2019):

- *Pregnancy or breastfeeding.* A delayed or missed period can be an early sign of pregnancy. Breastfeeding typically delays the return of menstruation after pregnancy.
- *Eating disorders, extreme weight loss, or excessive exercising.* Eating disorders (such as anorexia nervosa), extreme weight loss, malnutrition, and increased physical activity can disrupt menstruation.
- *Polycystic ovary syndrome (PCOS).* This common hormonal disorder can cause small cysts (fluid-filled sacs) to develop on the ovaries and irregular menstruation.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- *Premature ovarian failure.* Premature ovarian failure refers to the loss of normal ovarian function before age 40 years. Individuals who have premature ovarian failure, also known as primary ovarian insufficiency, may have irregular or infrequent periods for years.
- *Pelvic inflammatory disease (PID).* This infection of the upper reproductive organs (uterus, fallopian tubes, or ovaries) can cause pain, discharge, and irregular menstrual bleeding.
- *Uterine fibroids.* Uterine fibroids are noncancerous growths of the uterus. They can cause heavy, prolonged menstrual periods and bleeding between periods.

There is no scientific rationale supporting abstinence from sexual activity during menses. Many females enjoy sex during menses owing to the increase in vascularity in the pelvic region, which heightens enjoyment. Males may also enjoy the warm wetness the menstrual flow provides to the vagina. If flow is heavy, a diaphragm can be used to hold it back during sexual activity, or a towel can be used to protect bedding. Some females who experience abdominal cramping during menses, called *dysmenorrhea*, find that sexual activity and orgasm relieve their discomfort.

In May 2007, the U.S. Food and Drug Administration (FDA) approved the first oral contraceptive designed to be taken 365 days a year by those who want to avoid menstruating altogether. Females who use the drug do not have regular menstrual periods, although they may have breakthrough bleeding (spotting or light bleeding). While there are obvious advantages to not having menstrual periods, females should be counseled that there are no long-term safety data on these drugs. Risks are thought to be similar to those of conventional oral contraceptives: an increased incidence of blood clots, heart attacks, and stroke, especially in those who smoke. Positive benefits may include lowering the risk for ovarian cancer and endometrial cancer (National Cancer Institute, National Institutes of Health, 2018; FDA, 2021).

Premenstrual Syndrome and Premenstrual Dysphoric Disorder

Premenstrual syndrome (PMS) is characterized by the appearance of one or more of the following symptoms several days before the onset of menstruation: (1) emotional symptoms such as depression, irritability, anxiety, changes in sleep habits, changes in sexual desire, poor concentration, crying, anger, and social withdrawal; and (2) physical symptoms such as appetite changes, breast tenderness, bloating and weight gain, aches and pains, swelling, acne, gastrointestinal issues, and fatigue (The American College of Obstetricians and Gynecologists [ACOG], 2021). An estimated 85% of menstruating females experience at least one PMS symptom with their monthly cycle; up to 12% of menstruating females present with premenstrual disorders (Hofmeister & Bodden, 2016; Office on Women's Health, U.S. Department of Health & Human Services [USDHHS], 2018). PMS is diagnosed by a health care provider by establishing a pattern of symptoms that are associated with menstruation. In order to establish a pattern, providers frequently ask the patient to keep a log of their symptoms and menstrual cycle.

Premenstrual dysphoric disorder (PMDD) differs from PMS primarily in that it is a DSM-5-classified diagnosis by the American Psychiatric Association, and its symptoms are primarily psychiatric in nature. Some studies have shown that PMDD is related to serotonin levels, and the symptoms reported are more disabling than symptoms reported with PMS.

Management of PMS and PMDD are primarily symptom-management focused, with individuals diagnosed with PMDD benefitting from antidepressants that address serotonin levels (ACOG, 2021; Hofmeister & Bodden, 2016; Office on Women's Health, USDHHS, 2018). Nurses have a great role to play in researching PMS and PMDD and ensuring that females and the public correctly understand their effects.

Sexual Response Cycle

The physiologic responses to sexual activity of females and males can be more similar than different (Fig. 46-3). The body's response is essentially the same regardless of the source of stimulation; that is, fantasy, masturbation, and sexual intercourse can all bring about the same body reactions. The sexual response cycle is not limited to the genital organs but is a total body response that causes many physiologic changes throughout the body. The classic sexual response cycle outlined by Masters and Johnson (1966) is linear in nature and has four phases: excitement, plateau, orgasm, and resolution; there is a smooth progression from one phase to the next. Although only physiologic responses are discussed here, the emotional and mental involvement of sexual response contributes a great deal to the pleasure and satisfaction of sexual activity.

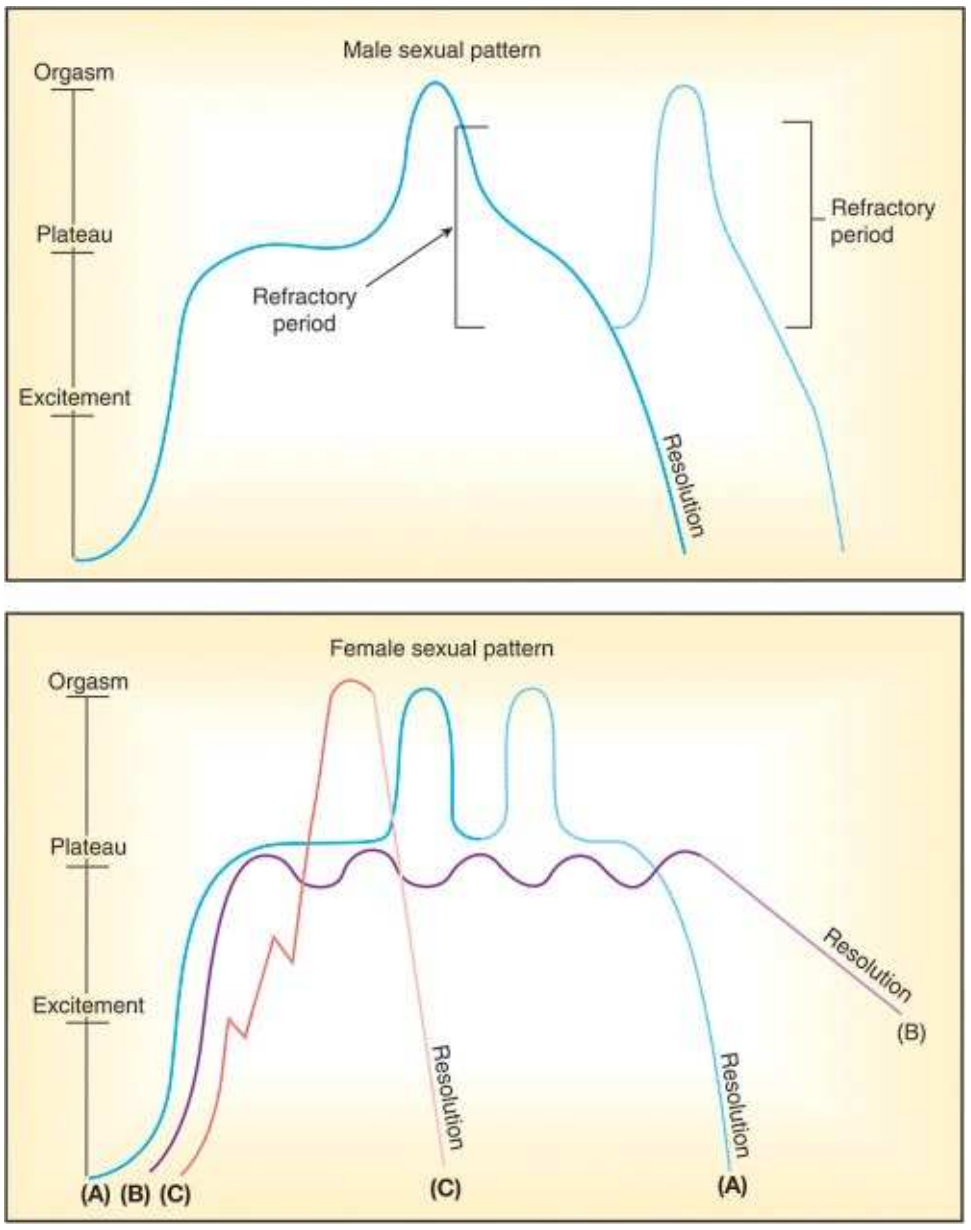

FIGURE 46-3. Male and female sexual response patterns. Three female patterns are shown: **(A)** Steady progression to plateau stage is followed by intense orgasm; subsequent orgasms may occur; resolution is slower. **(B)** Slower progression to plateau stage is followed by minor surges toward orgasm, causing prolonged pleasurable feelings without definitive orgasm; resolution is slowest. **(C)** Rapid progression to plateau stage with some peaks and dips; one intense orgasm follows with rapid resolution. This most closely resembles the male pattern.

The human body contains many **erogenous zones**, areas that when stimulated cause sexual arousal and desire. The genitals are an obvious source of sexual pleasure for all people, but other areas of the body are also considered erogenous zones. The skin is the largest erogenous zone. Other areas include the ears, lips, thighs, and breasts. Some people can reach orgasm simply by stimulation of nongenital erogenous zones.

The most important body organ for sexual arousal and stimulation is the brain. Engagement of the brain in arousal allows people the freedom to enjoy a sexual experience but may also prevent satisfaction because of inhibitions, doubts, and guilt.

Excitement

The excitement phase is initiated by erotic stimulation and arousal. Some of the physiologic changes common in all people include an increase in heart rate and blood pressure, and the appearance of a pink to red flush to the skin. This sex flush, which is more evident in females than in males, spreads over the face, neck, back, and upper torso. Congestion of the genitals with increased blood flow begins in the excitement phase and causes even more arousal. The length of the excitement phase varies greatly among people and even from one experience to another.

During the excitement phase, the female breasts swell, and the nipples become erect and hard to the touch. Lubrication of the vagina seeps to the outside of the body along the vulvar creases and makes stimulation of the genitals more pleasurable by decreasing friction. The upper two thirds of the vagina enlarge and expand. The clitoris enlarges and emerges slightly from the clitoral hood. The labia also enlarge and separate and turn a deep rosy red with arousal.

The first obvious sign of arousal in the male is an erection of the penis caused by increased pelvic congestion of blood. The scrotum noticeably elevates, thickens, and enlarges. The skin of the penis and scrotum turns a deep reddish purple in response to congestion and arousal. Male nipples may also harden and become erect.

Plateau

The intensity of the plateau phase is greater than that of excitement, but not enough to begin orgasm. Desire and arousal continue to build and intensify. This phase varies from a few minutes to 15 to 20 minutes. In the female, the clitoris retracts and disappears under the clitoral hood. It is thought that the clitoris performs in this mysterious way as the body's protection against overstimulation. In the male, secretions from Cowper's glands may appear at the glans of the penis during the plateau phase.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Orgasm

The term **orgasm** defines the climax and sexual explosion of the tension that has been building over the preceding phases. Orgasm lasts only seconds but is an extremely intense reaction. Characteristics of the orgasm phase are the involuntary spasmodic contractions of the genital organs. The number of contractions felt by the person depends on the intensity of the orgasm.

The orgasm phase in the female begins with a heightened feeling of physical pleasure, followed by overwhelming release and involuntary contractions of the genitals. Loss of muscular control may cause spastic contractions and twitching of the arms and legs. The number of contractions can be as few as 4 or as many as 20. Areas of the body that contract spasmodically are the uterus, anal sphincter, rectum, and urethral sphincter. It is believed that females achieve orgasm in a variety of ways. Although some females can achieve orgasm by penile thrusting in the vagina alone, most individuals need clitoral stimulation to reach orgasm.

During orgasm in the male, involuntary spasmodic contractions occur in the penis, epididymis, vas deferens, and rectum. The male orgasm is most often accompanied by ejaculation of semen from the urinary meatus of the penis. Ejaculation and orgasm usually, but not necessarily, occur at the same time.

Resolution

The resolution phase is characterized by a return to the normal body functioning present before the excitement phase. Feelings of relaxation, fatigue, and fulfillment are common. Some people have a need to be held, fondled, and caressed. Physical demonstrations of affection may initiate the sexual response cycle once again. The female body is physiologically capable of immediate response to sexual stimulation. Because of this, many females can achieve multiple orgasms. Males experience a period during which the body does not respond to continued sexual stimulation, called the refractory period. The length of the refractory period varies from a few minutes to longer, even days.

Female Sexual Response: A Nonlinear Model

Basson's (2000) Nonlinear Model of female sexual response is important because it acknowledges differences in the sexual responses of women, especially those who have been in a long-term relationship. Basson specifically focuses on distinguishing *different* from *dysfunction*. According to her model, women who do not have traditional sexual desire (thoughts and fantasies), but who are able respond to sexual stimulation, do not necessarily have a sexual dysfunction. Sexual desire differs among women—for some it may revolve around the desire for intimacy or manifest as responsive desire (i.e., desire that is responsive to cues, behaviors, and other stimuli). This means a woman may engage in sex based on their choice to respond to other needs (such as emotional closeness), not necessarily the biological need to experience sexual arousal or release. Vaginal lubrication and other genital changes that are frequently considered signs of arousal may not be considered important by the woman, but this does not mean they have a sexual dysfunction. Orgasm is not essential for sexual satisfaction for many women. Basson's Nonlinear Model emphasizes the effect of emotional intimacy, sexual stimuli, mental excitement, and relationship satisfaction on the female sexual response.

Childbearing Considerations

All sorts of questions surround childbearing, and the ability (or lack of ability) to procreate can put great pressure on a sexual relationship: Are we ready to be parents? What does it mean to be a responsible parent—especially in this age when an increasing number of prenatal interventions are available to maximize fetal outcomes? Should we choose life partners only if genetic testing reveals a good match for reproduction? If we choose to be sexually active and not have children, what are the best means to prevent unwanted pregnancies? If we become pregnant and choose not to continue the pregnancy, what are our options? If we desperately want a child and discover one or both to be infertile, what are our options? What are our options if we are a same-sex couple? Who donates sperm or eggs and who carries the baby to term? The age of biotechnology promises *designer babies* and raises difficult questions for individuals and society. People frequently look to nurses for help in sorting through how to respond to these challenges. Experienced nurses are good at detecting when a fear of pregnancy or inability to conceive is interfering with a couple's normal sexual expression, or when a changing developmental stage (e.g., menopause) is interfering with normal sexual expression.

Sexually Transmitted Infections

Sexually transmitted infections (STIs), or sexually transmitted diseases (STDs) are infections that are spread primarily through sexual contact. Although *STIs* and *STDs* are often used interchangeably, in health care, STI is more commonly used because not every STI results in disease or has active symptoms.

STIs are among the most common infectious diseases in the United States today. Each of these infections is a potential threat to a person's immediate and long-term health and well-being, and can lead to severe reproductive health complications, such as infertility. Prevention and counseling involve obtaining a sexual history focused on the 5Ps: partners, practices, protection from transmitted infections, past history of STIs, and pregnancy intention (CDC, 2021c). Check out this guide from the CDC that walks through the 5Ps and taking a sexual history: https://www.cdc.gov/std/treatment/SexualHistory.pdf

According to the National Institute of Allergy and Infectious Diseases (NIAID, 2015–2022), understanding the basic

facts about STIs—the ways in which they are spread, their common symptoms, and how they can be treated—is the first step toward prevention. News releases, fact sheets, research studies, and other NIAID-related materials are available on the NIAID website at www.niaid.nih.gov. NIAID recommends understanding at least five key points about all STIs in the United States today:

. STIs affect people of all backgrounds and economic levels. They are most prevalent among teenagers and young adults.
. The incidence of STIs is rising, in part because in the last few decades, young people have become sexually active earlier yet are marrying later. In addition, divorce is more common. The net result is that sexually active people today are more likely to have multiple sex partners during their lives and are potentially at risk for developing STIs.
. STIs frequently cause no symptoms, particularly in women. When symptoms develop, they may be confused with those of other diseases not transmitted through sexual contact. Even when an STI causes no symptoms, a person who is infected may be able to pass the disease on to a sex partner. That is why many doctors recommend periodic testing or screening for people who have more than one sex partner.
. Health problems caused by STIs tend to be more severe and more frequent for females than for males, in part because the frequency of asymptomatic infection means that many females do not seek care until serious problems have developed.
  - Some STIs can spread into the uterus and fallopian tubes to cause pelvic inflammatory disease (PID), which is a major cause of both infertility and ectopic (tubal) pregnancy. The latter can be fatal.
  - STIs in anyone with a cervix may also be associated with cervical cancer. One STI, human papillomavirus (HPV) infection, causes genital warts and cervical/other genital cancers.
  - STIs can be passed from a female to their baby before, during, or immediately after birth; some of these infections of the newborn can be cured easily, but others may cause a baby to be permanently disabled or even die.
. When diagnosed and treated early, many STIs can be treated effectively. Some infections have become resistant to the drugs used to treat them and now require newer types of antibiotics. Experts believe that having STIs other than HIV increases a person's risk for becoming infected with the HIV virus (NIAID, 2015–2022).

Prevention counseling for STIs and HIV is essential and should be provided in a nonjudgmental, empathetic manner that accounts for the person's culture, primary language, sex, gender identity, sexual orientation, age, and intellectual development level. It should be offered to all sexually active adolescents and to all adults who have an active STI, have had an STI in the past year, or who report multiple sex partners (CDC, 2021c). There is a renewed emphasis on partner services, which includes clinical evaluation, counseling, diagnostic testing, and treatment for individuals in a sexual network. Expedited partner therapy, focused specifically on chlamydia and gonorrhea, permits a patient to obtain prescribed medication for their partner(s) who are unlikely to seek clinical evaluation. Partner services require collaboration between patients, providers, and public health partners (CDC, 2021c). Primary prevention strategies aim to reduce the spread and potentially devastating effects of untreated STIs. Recent guidelines outline specific strategies for prevention and treatment of STIs in specific populations including adolescents, children, men who have sex with men (MSM), women who have sex with women (WSW), women who have sex with women and men (WSWM), transgender or gender diverse persons, and those who are pregnant or incarcerated (CDC, 2021c). Table 46-2 lists common types of STIs and their signs and symptoms.

Consider **Paul Rojas,** a young adult man who has told the health care team he is gay, was diagnosed with AIDS. The nurse would need to assess the patient's sexual practices and instruct him about methods to prevent the transmission of HIV/AIDS. In addition, the nurse would need to assess for potential STIs that could increase his ability to transmit HIV to a HIV-negative sexual partner.

Sexual Dysfunction

Sexual dysfunction is a problem that prevents a person or couple from engaging in or enjoying sexual intercourse and orgasm. Dysfunctions might occur as a result of physiologic malfunctions, conflicts with cultural norms, interpersonal problems, or any combination of these. Anxieties and fears concerning the sexual act are almost always present. Patients with severe sexual dysfunctions require intensive professional therapy from a qualified sex therapist.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Male Primary Sexual Dysfunctions

ERECTILE DYSFUNCTION

Erectile dysfunction (ED), also called **impotence**, is the inability of a male to attain or maintain an erection to such an extent that they cannot have satisfactory intercourse. Common causes of impotence (which may be physiologic or psychological) include various illnesses, treatments for these illnesses, and personal anxieties. New medications have revolutionized treatment for erectile dysfunction.

Table 46-2 Sexually Transmitted Infections

DISEASE/INFECTION	CHARACTERISTICS
Human immunodeficiency virus (HIV)[a]	• HIV-1/HIV-2 Ag/Ab combination assay—begin antiretroviral therapy (ART) as soon as possible for all people • Higher risk in those who engage in needle-sharing and sexually active gay, bisexual, and other men who have sex with men (MSM)—recommend at least annual testing • Recommend testing for all pregnant persons in the United States at the first prenatal visit; test when another STI is diagnosed • Consider pre-exposure prophylaxis (PrEP) and post-exposure prophylaxis (PEP) with any STI diagnosis; begin ART and behavioral/psychosocial services as soon as possible with HIV infection • Asymptomatic or fatigue, diarrhea, weight loss, enlarged lymph nodes, fever, anorexia, and night sweats
Bacterial vaginosis (BV)	• Imbalance of bacteria (alters flora in the vagina) • Symptoms in females: foul-smelling, thin, grayish white vaginal discharge • Males typically asymptomatic • Treat with metronidazole (abstain from alcohol when taking)
Chlamydia[a]	• *Chlamydia trachomatis*—intracellular bacteria • Primarily affects young people ages 15–24 years • Many people are asymptomatic • Symptoms in females: vaginal discharge, burning on urination, urinary frequency, dysuria, and urethral soreness • Symptoms in males: penile discharge, burning sensation with urination, pain and swelling in testicles
Cytomegalovirus (CMV)	• A virus in the same family as herpes and Epstein–Barr • A first-time infection may cause mononucleosis, a mild illness with fever and swollen glands, liver, and spleen • May be asymptomatic • Not exclusively sexually transmitted; can be associated with certain pelvic inflammatory disease (PID) cases
Genital herpes	• Herpes simplex virus type 2 (HSV-2) typically causes genital herpes • Can be caused by HSV-1 through oral sex; HSV-1 typically leads to cold sores • Chronic, lifelong viral infection—systemic antiviral medications • Lesions develop around the genitals, rectum, or mouth • Appear as single or multiple painful vesicles, which rupture and form ulcer-like lesions; these form scabs as they heal • First infections last about 10–14 days, whereas subsequent infections are shorter in duration

	• Recurrences are usually preceded by prodromal symptoms of tingling and fullness
Gonorrhea[a]	• Gram-negative bacteria *Neisseria gonorrhoeae* • Primarily affects young people ages 15–24 years • Many people are asymptomatic • Symptoms in females: most have no symptoms; dysuria, abnormal menses, vaginal discharge, pelvic inflammatory disease • Symptoms in males: purulent penile discharge, dysuria, frequency of urination • Symptoms of pharyngitis if oral sex was practiced • May be accompanied by chlamydial infection • Newborns exposed at birth are at risk for blindness and pneumonia • Untreated gonorrhea can result in infertility, skin rash with lesions, and acute arthritis
Human papillomavirus (HPV)	• A DNA virus; vaccine recommended for everyone • Most people who have had sex acquire HPV, but are asymptomatic; HPV resolves spontaneously • Genital warts: pale, soft, papillary lesions found around the internal and external genitalia and perianal and rectal areas of the body; vary in size • Females with HPV are at risk for cervical (and other) cancer
Syphilis[a]	• *Treponema pallidum*, a spirochete detected through serologic blood test • Syphilis rates rising among gay and bisexual males and pregnant people • Stages of disease if left untreated: • *Primary:* Single painless genital lesion 10 days to 3 months after exposure • *Secondary:* Generalized skin rash, enlarged lymph nodes, fever that may appear 2–4 weeks after appearance of primary lesion; may last for several years • *Latent:* Usually no clinical symptoms present for as long as 20 years • *Tertiary:* If left untreated, syphilis can lead to severe medical problems that affect the heart, brain, nervous system, and blood vessels
Trichomoniasis (“Trich”)	• *Trichomonas vaginalis*, a protozoan with flagella • May be identified on Pap smear • Males typically asymptomatic • Symptoms in females: foul-smelling vaginal discharge, thin, foamy, and green in color, causes itching of vulva and vagina, burning on urination and dyspareunia; strawberry-appearing cervix may be seen on colposcopy.

[a]Reportable diseases in every state.

Recall **Jefferson Smith,** the patient with diabetes and hypertension who is having problems with erections. The nurse would review the pathophysiologic effects of diabetes and hypertension on sexual response. The nurse would also evaluate his current status, including a review of all medications that he is taking, to determine possible contributory factors.

PREMATURE EJACULATION

Premature ejaculation is a condition in which a male consistently reaches ejaculation or orgasm before, or soon after entering the vagina or other orifice. The result is that the partner usually does not have time to reach sexual satisfaction. Causes of this problem are rarely physical. See the Nursing Care Plan 46-1 for Pete Manheim on pages 1896–1899 for a discussion of a related phenomenon, nocturnal ejaculation.

DELAYED EJACULATION

Delayed ejaculation, also called ejaculatory incompetence, refers to a male's inability to ejaculate in an expected time frame. The causes of this problem are similar to those of impotence. When it occurs after experiencing normal ejaculations, the cause is most likely due to interpersonal problems.

Female Primary Sexual Dysfunctions

INHIBITED SEXUAL DESIRE

Inhibited sexual desire consists of an inhibition in sexual arousal so that congestion and vaginal lubrication are absent or minimal. Causative factors may be anxiety, negative emotions, fear, interpersonal problems, or physical factors. Orgasmic dysfunction is defined as the inability of a female to reach orgasm. The causes are similar to those of inhibited sexual desire.

DYSPAREUNIA

Dyspareunia is painful intercourse. Although it is most often described by females, some males may also suffer from this disorder. The cause is usually physical, although psychological problems such as fear and anxiety can cause pain.

Consider **Amy Liu,** the woman who had a hysterectomy and is experiencing pain on intercourse. The nurse would review the patient's history to determine if the problem is physiologic, secondary to changes in the reproductive tract from surgery, or psychological, secondary to the changes in self-concept and her report of not feeling "like a woman anymore."

VAGINISMUS

Vaginismus is a rare condition in which the vaginal opening closes tightly and prevents penile penetration. Vaginismus is due to involuntary spastic contractions of the muscles at and around the vaginal opening and the levator ani muscles. The cause of vaginismus may be physical, psychological, or both.

VULVODYNIA

Vulvodynia, a chronic vulvar discomfort or pain characterized by burning, stinging, irritation, or rawness of the female genitalia that interferes with sexual activity, is particularly problematic because little is known about its cause or treatment.

Effects of Illness, Injury, and Medications

A healthy body, mind, and emotions are necessary for sexual wellness. A primary sexual dysfunction can affect a person's sexual expression. Similarly, any trauma or stress that interferes with a person's ability to perform daily functions will also affect the expression of sexuality. Illness is no exception.

Diabetes Mellitus

Diabetes mellitus (DM) is a hormonal disease in which an inadequate amount of insulin is secreted by the pancreas. Although almost all hormonal disorders affect sexuality in some way, diabetes is the most prevalent and well known. ED, or impotence, is a great concern among those with type 2 diabetes. Treatment to date depends largely on the degree of erectile ability lost. Some individuals may be candidates for a penile prosthesis, which was developed in 1973. The prosthesis is surgically implanted below the base of the penis, and inflation of the device produces an erection when sexual activity is desired. Pharmacologic management (e.g., sildenafil, vardenafil, or tadalafil) may also be indicated.

Think back to **Jefferson Smith,** the patient with diabetes and hypertension. The nurse would explore with Mr. Smith his feelings about the effect of his disorder on his sexual function and sexuality. Additional consultation with other members of the health care team would be necessary to determine the most appropriate plan for treatment of Mr. Smith's impotence.

Females with type 2 diabetes may also experience loss of capacity for orgasm (orgasmic dysfunction). Difficulty experiencing arousal and loss of vaginal lubrication have also been reported. Females with diabetes are more prone to urinary tract or vaginal infections, which can cause discomfort during coitus.

Cardiovascular Disease

Cardiovascular disease is prevalent in North America, and the sexual response cycle can greatly increase the demands on the heart and other structures. A person with a cardiovascular disease may experience much anxiety over the effect the illness will have on sexuality and sexual functioning.

HYPERTENSION

The most significant difficulty a person diagnosed with hypertension faces regarding sexuality is that the medication used to control the disease frequently causes a change in sexual functioning. These sexual dysfunctions may be relieved by modifying the dose of the medication or switching to a different medication.

Consider **Jefferson Smith,** the patient with a history of diabetes and hypertension. The nurse would obtain a complete medication history from the patient to determine if his pharmacologic therapy is the underlying cause of his impotence or if the medication is contributing to a preexisting problem associated with his diabetes. This investigation would provide information about whether an adjustment in medication dosage might minimize or alleviate Mr. Smith's impotence.

MYOCARDIAL INFARCTION

The primary goal after a myocardial infarction (MI), or heart attack, is to allow the heart ample time to heal. Activities of daily living, including sexual activity, should be resumed gradually, and stressors such as overexertion, alcohol consumption, and emotional upheavals should be avoided. After an uncomplicated MI, sexual activity may begin at

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

about the third week of recovery, beginning with masturbation to partial erection in the male. In general, this activity is gradually increased until 3 months after the MI, when sexual intercourse may be resumed. A comfortable position that places the least stress on the affected partner should be used.

Diseases of the Joints and Mobility

Joint diseases and disorders affect people of all ages. Pain, fatigue, stiffness, and loss of range of motion can accompany any of the dozens of known diseases of the joints. The disease itself does not affect sexual functioning, although the manifestation of it can cause discomfort and anxiety.

Surgery and Body Image

Surgery is performed to remove diseased tissue and repair body organs, usually requiring an incision with resulting scars. The most devastating kinds of surgery are those used to remove cancerous tissue and surrounding structures. Patients are almost always distressed about a diagnosis of cancer and possible death. After surgery, patients need to adjust to major alterations in their bodies. Changes in body image also affect a person's self-perception as a sexual being.

Remember **Amy Liu,** the woman who had had a hysterectomy. The uterus, because it is a female reproductive organ, is often associated with childbearing and may trigger a specific grieving response. The nurse would interpret the significance of the uterus to the patient's self-concept and how the surgery to remove it has affected her overall feelings of femininity and womanhood. Using this information, the nurse would then correct any misconceptions that Mrs. Liu may have about this reproductive organ and develop an appropriate teaching plan.

Mastectomy is a surgical procedure to remove a breast and surrounding tissue. After such a surgery, the return to sexual functioning depends on many factors, such as support of a sexual or life partner(s), the value placed on the breast by either partner, and fear of discomfort during sexual activity. Allowing the patient time to grieve the loss of the uterus or breast(s) is appropriate and may help with long-term coping.

An ostomy is a surgical opening placed on the outside of the body to allow for the passage of secretions and elimination into a closed drainage bag. Grieving over the loss of the natural means to eliminate waste, such as urine or feces, accompanies learning to live with an obvious artificial device. Many people are anxious as to how this apparatus will affect their sex lives and how accepting their partners will be of it. Odor and leakage concerns need to be addressed to increase comfort with the device.

Spinal Cord Injuries

Thousands of people are victims of spinal cord injuries each year as a result of various types of accidents. This type of injury almost always results in some degree of permanent disability. People with SCI face multiple adaptations in their lifestyles, including those related to mobility, bowel and bladder control, sexual functioning, and role expectations. The extent of sexual response that remains after a spinal cord injury depends primarily on the level and extent of the injury. Ejaculation and orgasm are most likely to remain with low spinal injuries. Females are more likely to experience orgasm than males, but they more frequently report a lack of physical sensations during the excitement phase than do males. Many people find that other erogenous zones become more easily stimulated after the injury.

Chronic Pain

Many chronic illnesses are accompanied by constant pain, and a person with persistent pain may not desire any sexual contact. However, the desire for human warmth and contact does not cease because of pain. Altered or modified positions for coitus are sometimes necessary; discussing these positions with patients can be an important part of implementing the nursing process, reviewed later in this chapter.

Mental Illness

Various psychological and physical disorders can cause mental illness. The mind plays a powerful role in sexuality; any disruption of its functioning will no doubt cause some disturbance in sexual functioning. Even mild depression can affect desire and sexual functioning. At times, patients with mental illness act out in a sexual manner, such as touching

themselves or removing their clothing at inappropriate times and places. Sometimes, it is difficult for the partner of a patient who has developed a mental illness to continue the sexual relationship. People afflicted with Alzheimer disease can lose the memory of any contact with a partner or spouse.

Medications

Some medications have side effects that may affect sexual functioning. These include nitrates, anticonvulsants, antidepressants, antihistamines, antihypertensives, antipsychotics, antispasmodics, barbiturates, and narcotics. Recreational drugs including cocaine, alcohol, and marijuana are used by some to heighten the sexual experience. These drugs can have serious and even deadly side effects. While some use alcohol to release inhibitions and to increase sexual arousal and desire, heavy drinking can decrease libido and negatively affect sexual functioning.

SEXUAL HARASSMENT

Harassment is any annoying or distressing comment or conduct that is known, or should be known to be unwelcome. **Sexual harassment** is unwelcome behavior that is based on a person's sex or gender. This type of harassment usually occurs in the context of an asymmetrical relationship in which one person has more formal power than the other (e.g., a faculty member over a student) or more informal power (e.g., one peer over another). Sexual harassment can be directed toward people of any age, any gender, and any sexual orientation. There are two forms of sexual harassment: quid pro quo and environmental harassment (also called a *hostile environment*). Quid pro quo means something given or withheld in exchange for something else. *Quid pro quo harassment* occurs when a person's employment or well-being is dependent on agreeing to unsolicited and unwelcome sexual demands. This type of harassment is typically initiated by a person in a position of authority who offers either direct or indirect reward or punishment based on the granting of sexual favors. Quid pro quo harassment is a clear abuse of power and is legally, morally, and ethically wrong.

Hostile work environment occurs when sex- or gender-based behaviors create a hostile, intimidating environment that hurts a person's work performance, classroom performance, or general sense of well-being. In the workplace, for example, the negative behaviors in hostile environment harassment are not directly linked to job-related consequences; instead, the employee's willingness to suffer the experience of the demeaning environment becomes a condition of employment. This type of harassment is not necessarily caused by a person with formal power. A hostile environment is sometimes difficult to identify, as it is not always easy to determine when offensive speech or behavior actually turns to true harassment. In order to be considered a hostile work environment, the behaviors must be unwanted, frequent (not a one-time event), and pervasive. Coworkers and peers can create a hostile environment for a member of the group through the following:

- Unwelcome sexually oriented and gender-based behaviors
- Sexual bantering
- Sexual jokes
- Offensive pictures and language
- Sexual innuendoes
- Sexual behavior
- Unwanted attention such as asking for dates constantly, physically blocking movement, or creating unwanted interactions

Effects of Harassment

Harassment can cause feelings of helplessness, worthlessness, and guilt in the victim. This can often lead to less career satisfaction and feelings of loss of control. Anger is commonly experienced by those who have been harassed, which may lead to requests for transfer, resignation, or withdrawal from the environment where the harassment occurs. In many cases, job performance is affected due to reduced levels of concentration. Loss of job motivation and skill confidence, along with reduced job satisfaction and organizational commitment, are common.

Responding to Harassment in the Nursing Environment

Inappropriate sexual behavior by a patient may cause the nurse to respond with a range of actions from passive avoidance to aggressive retaliation. An assertive response that supports the nurse in maintaining self-respect, while encouraging the patient to accept responsibility for their behavior, is recommended.

. *Be self-aware*: Do not deny feelings about being harassed.
. *Confront:* Provide feedback to the patient in a nonthreatening way and clearly state what behavior is or is not acceptable.
. *Set limits*: Define clear and reasonable consequences that will be enforced if the behavior continues.
. *Enforce the stated limits*: Maintain boundaries.
. *Report*: Document the incident and submit to supervisor.

Colleagues may also be a source of harassment. The objective of employers should be to create a positive work environment that is characterized by mutually respectful behavior. Many have taken steps to eliminate hostile work

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

environments by educating employees, developing policies against workplace harassment, and outlining guidelines for responding to sexual harassment.

- If harassed by a coworker, confront the behavior immediately. An assertive statement is sometimes sufficient to stop the behavior.
- If the harassment continues, document the date and time, and describe the behavior.
- Consult a supervisor not involved in the harassment.
- If the harassment still does not stop, file a grievance with administration.
- Seek legal advice if all previous efforts to stop the behavior have been unsuccessful. Sexual harassment is illegal and you have the right to ask for legal representation.

NURSE AS ROLE MODEL

Nurses' attitudes, biases, and prejudices regarding sexuality are readily transmitted to patients through their actions, manner of speech, and avoidance of certain circumstances or types of discussion (see Focused Critical Thinking Guide 46-1). A nurse's knowledge about sexual issues can inhibit or promote discussions of sexual health. The nurse who does not have a sound knowledge base of reproductive anatomy and physiology, sexual response, sexual expression, and other issues surrounding sexuality will be unable to assess, teach, or counsel patients with sexual concerns.

46-1 Focused Critical Thinking Guide

Sexuality and Nonjudgmental Nursing Care

A 33-year-old man with AIDS who is living alone at home asks you, the visiting nurse, about the nurse who was substituting for you during your vacation. "I don't like to complain, but he was overly friendly—if you get what I mean…. I wasn't comfortable with the way he was touching me, and I'd rather not have help with my bath than have him back here." You have to decide how to respond.

1. Identify goal of thinking

Clarify what the patient is saying and make a judgment about the behavior behind his concern so that you can respond appropriately.

2. Assess adequacy of knowledge

Pertinent circumstances: You have been visiting the patient for the last 2 months following his discharge from a local hospital because of AIDS-related complications. Apart from his clinical picture, you know very little about the patient, who has always seemed private and reserved during your visits. You feel sorry that the patient is as sick as he is at this point in his life, and your instinct is to trust him. You really don't know the colleague who was substituting for you because he was newly hired.

Prerequisite knowledge: Before you can make a judgment about the patient's concern, you need to know more about what actually happened between your colleague and him. You do not know your colleague well because he is a new hire and has been working in the facility for only 3 months. You have heard reports that he is gay. You know that the patient is single, but do not know his sexual orientation. You need to talk with your colleague to get his description of his encounter with the patient. You also need to know more about what touch means to both the patient and your colleague because culture and individual preference can profoundly influence the meaning different people give to touch.

Room for error: Life and death do not hinge on how you respond to this patient. However, the well-being of the patient and your colleague's reputation are at stake, so the matter is grave.

Time constraints: You must make some immediate response to the patient. Because you do not have sufficient information to evaluate what happened, you should not feel pressured to make a definitive response. The patient's well-being will not be jeopardized if you postpone a complete response until you have investigated the complaint.

3. Address potential problems

The most serious obstacles to critical thinking in this situation would be forgoing a systematic reasoning process and immediately moving to make false assumptions about sexuality, sexual expression, and gay male nurses. Your tendency to "go to bat" for patients and to believe whatever a patient tells you (no matter what) may result in your unfairly and prematurely judging a colleague.

4. Consult helpful resources

Your colleague is the first resource you should consult because you need to hear his side of the event before you can think critically about what happened. When you do meet with him, he thanks you for bringing up the subject

because he was similarly disturbed by his encounter with this patient. "I guess I'm a touchy-feely kind of guy and generally find that patients respond well to human touch. In the past, patients have told me how much it means to them to have someone massage their back, stroke a forearm, or greet them with a hug. Touch is certainly an integral part of my therapeutic style. I did sense rather quickly, though, that Jim didn't like to be touched and so I modified my approach. My sense, from a few comments he made, is that he's probably homophobic" (afraid of gay or lesbian people).

After listening to your colleague, you decide you need to learn more about touch, touch as a therapeutic intervention, and homophobia. You can consult the literature or local experts.

5. Critique judgment/decision

Wanting to explore the situation more fully, you responded to the patient initially by saying, "I am sorry that you felt uncomfortable by my colleague's care. I want to talk with him about his sense of what happened and will then discuss this with you when I return on Wednesday." After talking with your colleague, you are reasonably assured that he was not intending, inappropriately, to communicate anything of a sexual nature to the patient. On your return visit to the patient, you inform him about your research and judgment and say, "Touch can mean different things to different people. My sense is that Dave simply wanted to communicate that he cares. If he is going about this in the wrong way, he wants to know what he should be doing differently. He recognized that you weren't responding to touch, so he did alter his style, but your rapport was likely already negatively affected. We certainly don't want this to be a problem for you or any other patient. Would you like to talk more about this or to file a report?"

You initially thought you had four options: (1) agree at the outset that your colleague has behaved in a sexually inappropriate and unprofessional manner; (2) defend your colleague on principle alone; (3) investigate the incident and conclude that your colleague was in the wrong; or (4) investigate the incident and conclude that your colleague was in the right. You chose the fourth option and are relieved when the patient seems to accept your explanation. You are a bit bothered by the fact the nurse immediately labeled the patient homophobic, without providing any rationale, and you make a mental note to follow up on that comment. Two months later, when you receive a similar complaint from another male patient, you are troubled. You realize now that there was a fifth option, and that this is the one you should have taken. Irrespective of the fact you were convinced by your colleague's sincerity and good intent, you should have informed Dave, the nurse, that you needed to communicate this patient's concern to your supervisor so that if future incidents were reported, there would be a record of repeat complaints.

Recall **Paul Rojas,** the patient described in the Reflective Practice box on page 1862. The nurse caring for Mr. Rojas needs to be comfortable with their own sexuality to provide nonjudgmental care. In addition, the nurse needs knowledge about sexual orientation to develop an appropriate, unbiased plan of care that meets Mr. Rojas' needs.

Nursing goals to enhance interactions with patients and to promote individual sexual health are as follows:
The nurse will be able to:

- Feel comfortable as a sexual being.
- Develop self-awareness regarding sexual topics.
- Develop communication skills that promote discussion of sexual concerns with patients.
- Identify patients with problems related to sexuality and intervene competently and comfortably to meet these needs.
- Practice responsible sexual expression and respect the sexual expression of others.

NURSING PROCESS FOR THE PATIENT WITH A SEXUAL HEALTH NEED

Nurses who role model good health behaviors are more effective teachers. Use the display, Promoting Health 46-1, for yourself before using it with others.

Assessing

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Sexual History

The comprehensive health history should include information regarding a patient's reproductive and sexual health, depending on the circumstances in which the patient is receiving care. As a rule, three general categories of patients should have a sexual history recorded by the nurse:

- Any inpatient or outpatient receiving care for pregnancy, STI, infertility, or contraception
- Any patient experiencing sexual dysfunction
- Any patient whose illness will affect sexual functioning and behavior in any way

Information is best obtained from the patient by beginning with nonthreatening questions and progressing to more sensitive concerns (see Focused Assessment Guide 46-1). Patients usually have no difficulty answering questions regarding their bodies and general reproductive issues, such as, "When did your menstrual periods first begin?" Explain to patients that this information may help you develop the plan of care and identify any sexual problems or concerns. The assessment provides an excellent opportunity to teach by helping the patient confront fears.

Four general levels of sexual history are:

Level 1: Sexual history as part of a comprehensive health history—obtained by a nurse

Level 2: Sexual history—obtained by a nurse with education and training in sexuality

Level 3: Sexual problem history—obtained by a sex therapist

Level 4: Psychiatric/psychosocial history—obtained by a psychiatric nurse clinician

Each level acquires more specific information from the patient regarding sexual health, and thus requires the interviewer to have more sophisticated preparation and skills. The clinical nurse usually performs a sexual history on level 1.

The nurse sets the tone or atmosphere for the interview. The nurse's attitudes will greatly affect the patient's response to the sexual history; patients will be more cooperative if they sense the nurse's security and ease during the interview. Privacy is essential for the sexual history; doors should be closed, and no interruptions allowed. Sit close to the patient and speak in a quiet, relaxed, objective tone of voice. Use eye contact and open body posture. Explain to the patient that only providers directly involved with the care of the patient will have access to this information.

Promoting Health 46-1

SEXUALITY

Use the assessment checklist to determine how well you are meeting your sexuality needs. Then develop a prescription for self-care by choosing appropriate behaviors from the list of suggestions.

Assessment Checklist

☐ almost always ☐ sometimes ☐ almost never

☐	☐	☐	1. I feel positive about my sexual identity.
☐	☐	☐	2. I have satisfying relationships with others.
☐	☐	☐	3. I accept sexual needs as a normal part of life.
☐	☐	☐	4. I am comfortable with physical actions that indicate love and belonging (such as touching and hugging).

Self-Care Behaviors

1. Avoid stereotyping gender roles.
2. Learn the biological aspects of sexual functioning and consider the implications for those who are transgender.
3. Ask questions about sexual needs and sexual activity when necessary.
4. Enjoy close relationships with others who love you.
5. Give a hug to someone you love.
6. Accept touch from others as a sign of caring and affection.
7. Use contraceptives, condoms, and other barrier devices, and choose sexual partner(s) carefully.
8. Recognize how age, illness, or disability influences sexual needs and expression.

Focused Assessment Guide 46-1

SEXUALITY

Factors to Assess	Questions and Approaches
Reproductive history	Ask females their date of menarche, date of last menstrual period, duration and length of flow in days, number of pregnancies, living children, miscarriages, abortions, method of birth control. Ask males the number of children they have produced and method of birth control used. Ask all persons of childbearing age if they have any concerns about their fertility and determine whether there is any interest in the new reproductive technologies and genetic testing options. Consider the unique needs of persons who are transgender and integrate a holistic assessment.
History of sexually transmitted infections	"Do you or a sexual partner have a history of sexually transmitted infections?" "Many people today have questions about sexually transmitted infections that they are reluctant to express. Do you have any questions? Have you noticed any signs that might indicate a problem?"
History of sexual dysfunction	"Have you ever experienced a problem such as erectile dysfunction, failure to achieve orgasm, or pain during intercourse?"
Sexual self-care behaviors	"Do you know what your breasts (testicles) feel and look like normally?" "When was your last gynecologic (urologic) examination (Pap smear, mammogram)?" "Is there a family history of breast disease, ovarian cancer, testicular cancer, colon cancer?" "With all the attention on safer sex today and responsible parenting, many people have questions about their sexual self-care behaviors. Do you have any such concerns?" (It is important to ascertain whether patients possess the knowledge, attitudes, and skills necessary to promote their own sexual health and that of others.)
Sexual self-concept	
Sexual identity	"How do you feel about yourself as a man or woman? Is anything changing the way you feel about yourself?" Use appropriate terms and be open to conversations regarding gender when, for example, the individual does not consider gender in relation to their sexual identity or when gender and sex assigned at birth are not the same.
Sexual body image	"Many people have concerns about their sexual body image. Are you comfortable with your physical, sexual presentation?" "Have you experienced any physical changes (e.g., baldness, weight loss or gain, impotence, menopause, mastectomy, hysterectomy, sterilization) that are troubling to you?"
Sexual self-esteem	"We all have certain expectations of ourselves. Are you comfortable with the way you are currently expressing yourself sexually and meeting your sexual needs?"
Sexual role performance	"Has anything interfered with your ability to be a spouse, sexual partner, or other valued sex-related role?"
Sexual functioning	"It's not unusual for people with health concerns (name specific medical problem, if appropriate) to have questions related to sexuality and sexual functioning. Do you have any questions or concerns that I can help you with?" "Has anything (substitute the name of a specific disease, surgery, or medication, if appropriate) changed your ability to function sexually?" Asking patients if they have questions about resuming their usual sexual activity is an appropriate part of discharge planning for many patients.

Obtain reproductive health information first, followed by the sexual health history. The best approach is to begin with general open-ended questions and progress to more specific ones. Try to use the terminology used by the patient because the patient may be reluctant to admit not understanding certain terms for fear of appearing ignorant or foolish. For example, the patient may use the term "come" or "cum" to mean climax or orgasm. Although gender identity is different from biological sex or sexual identify, it may need to be discussed if working with a patient whose gender is different from their sex assigned at birth. For example, gender discussion will help determine preferred pronouns and ensure the appropriate biological questions are asked. Keep in mind that using "they" as a pronoun is becoming more common; checklists and other facility intake forms are evolving to reflect an expanding list of options. Use appropriate terms and allow the patient to provide whatever information the patient is comfortable sharing.

It is useful to begin questions with phrases such as "many people like" or "many people feel." This gives patients security in knowing they are not alone in how they feel and will encourage them to talk about their problems or concerns. For example, "Many people feel that it's helpful to discuss their concerns about sex with their partner. What do you think about this?"

One helpful structure for obtaining information about sexual problems follows:

- *Description of the problem:* "How would you describe the problem?"
- *Onset and cause of the problem:* "What do you think caused the problem, or what was happening when you first noticed it?"
- *Past attempts at resolution:* "What have you tried in the past to correct the problem?"
- *Goals of the patient:* "What do you wish to accomplish?"

A narrative format is generally used for recording a sexual history because it allows the interviewer to document the data in many of the patient's own words. If a patient is seeking help for a sexual problem, a more specific format is used to record information obtained by a skilled therapist.

Unfolding Patient Stories: Jared Griffin • Part 2

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Recall **Jared Griffin** from Chapter 7, a 63-year-old male who has undergone a right total knee arthroplasty. He is in a private room on contact precautions because he is a carrier of methicillin-resistant *Staphylococcus aureus* (MRSA). He is concerned about resuming sexual activity and transmitting the infection to his wife when he is discharged home. What communication characteristics portray professionalism and competency when the nurse is assessing sexual health? How can the nurse promote discussion of his sexual concerns? What patient education would the nurse provide for Jared?

Care for Jared and other patients in a realistic virtual environment: *vSim for Nursing* (thepoint.lww.com/vSimFunds). Practice documenting these patients' care in DocuCare (thepoint.lww.com/DocuCareEHR).

THE BETTER MODEL

The BETTER model was created to help oncology nurses conduct sexual assessments with their patients more effectively. The acronym BETTER (Mick et al., 2004) stands for the following:

Bring up the topic of sexuality so that patients know they can discuss sexuality openly.

Explain that you are concerned with all aspects of patients' lives affected by disease.

Tell patients sexual dysfunction can happen and that you will find appropriate resources to address their concerns.

Timing is important to address sexuality with each visit to let patients know they can ask for information at any time.

Educate patients about the side effects of their treatments and that side effects may be temporary.

Record your assessment and interventions in patients' medical records.

A few of the major dysfunctions and assessment priorities are briefly discussed in Table 46-3. Also see the Focus on the Older Adult display on page 1882.

Physical Assessment

Physical examination of the reproductive or genitourinary system is necessary for patients under the following circumstances:

- As part of a routine physical examination
- Annual gynecologic health care examination, including a Pap smear
- Suspected STI
- Suspected pregnancy
- Workup for infertility
- Unusual lump, discharge, or appearance of the genital organs noticed by the patient
- Request for birth control
- Change in urinary function

The examiner may routinely perform a complete physical examination along with assessment of the reproductive system if the patient has not had contact with the health care system within 1 year, or if the assessment findings from a complete examination would be useful in diagnosing something reported by the patient. See Chapter 27 for a detailed description of how to examine the female and male genitalia.

Initially, ask whether the patient has had this type of examination in the past (if this information is not evident in the patient's records). Depending on the patient's knowledge base, explain the progressive steps of the examination and what the patient may feel during the examination. This will give the patient some feeling of control and security during the examination. The nurse's responsibilities during an examination of the reproductive system are as follows:

- Provide information about the examination.
- Teach the patient.
- Provide support to the patient during the examination.
- Perform the examination or assist the examiner, if appropriate, with any procedures or laboratory studies.

Keeping the patient comfortable and respecting the patient's privacy and modesty should be primary nursing considerations. Some female patients may be uncomfortable with a male examiner, or vice versa, for religious, cultural, or other reasons. The examiner can adapt to such concerns, for example, by ensuring that a female nurse is in the room when a female patient is undergoing a pelvic examination by a male provider. Some patients who are transgender prefer to be seen by a provider who is known to be *LGBTQIA+ welcoming* or who provides transgender

care specifically, particularly when seeking a gynecologist or endocrinologist.

Diagnosing

The International Council of Nurses (ICN, 2019) groups sexual problems into several categories:

- *Problematic Sexual Behavior:* This problem arises when a person experiences or is at risk for a change in sexual health, which results in concern regarding their own sexuality. Sexual health is the integration of somatic, emotional, intellectual, and social aspects of sexual being in ways that are enriching and that enhance personality, communication, and love. This problem may result from problematic behavior or may be based on a knowledge deficit.
- *Impaired Sexual Functioning:* This problem presents when a person experiences or is at risk for change in sexual function (desire, excitation, or orgasm) that does not meet the sexual needs of the individual.

Table 46-3 Sexual Dysfunction and Nursing Assessment

SEXUAL DYSFUNCTION	ASSESSMENT PRIORITIES
Male	
Erectile dysfunction (impotence)	• Assess for history of diabetes, spinal cord trauma, cardiovascular disease, surgical procedure, or alcoholism. • Assess for use of certain medications such as antihypertensives, antidepressants, or illicit drugs. • Determine degree of mental depression that may be present. • Obtain specific information regarding the degree of impotence, length of time of disorder, or continuing life factors.
Premature ejaculation	• Assess what patient defines as the dysfunction and ability to control ejaculation. • Assess any causative relationship factors such as anxiety, guilt, lack of time, or new partner.
Delayed ejaculation	• Assess for history of neurologic disorders, Parkinson disease, or use of certain medications. • Use the same assessment priorities as for premature ejaculation.
Female	
Inhibited sexual desire	• Assess for use of oral contraceptives or other hormonal therapy, use of alcohol or certain medications. • Assess for history of sexual abuse, rape or incest, depression, or other sexual dysfunctions. • Assess any other contributing or relationship factors.
Orgasmic dysfunction	• Assess knowledge regarding sexual response cycle and anatomy. • Assess the communication pattern between the patient and partner(s). • Assess the usual sexual pattern and behavior between the patient and partner(s). • Assess any other contributing factors.
Dyspareunia	• Assess for history of diabetes, hormonal imbalance, vaginal infection, endometriosis, urethritis, cervicitis, or rectal lesions. • Assess for use of antihistamines, alcohol, tranquilizers, or illicit drugs. • Assess the patient's ability for vaginal lubrication during the sexual act. • Assess the patient's use of coital positions. • Assess the use of cosmetic or chemical irritants to the genitals, such as deodorant tampons, contraceptive creams or jellies, or condoms. • Perform physical assessment of internal and external genitalia. • Assess any other contributing factors.
Vaginismus	• Assess knowledge regarding anatomy and sexual response. • Assess the pattern of sexual activity: how often, level of arousal, orgasm.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- Assess the presence of other sexual dysfunctions.
- Assess for history of sexual abuse, trauma, or rape.
- Assess the patient's feelings regarding partner(s).
- Assess any other causative factors, such as fear of pregnancy, anxiety, or guilt.
- Perform physical assessment of internal and external genitalia.

Focus on the Older Adult

NURSING STRATEGIES TO ADDRESS AGE-RELATED CHANGES IN SEXUALITY AND SEXUAL FUNCTION

Factors that contribute to sexual dysfunction in the older adult are essentially the same as those that affect performance at any age: disease or mutilating surgery of the genitourinary tract, diverse systemic diseases, and emotional disturbances coupled with societal attitudes.

Age-Related Changes	Nursing Strategies
Use of multiple medications may impact on sexual desire and performance.	• Educate older adult patients, intimate partners, and family about the sexual side effects of specific medications. Sometimes a change in medication dosage or modification in the treatment regimen can reduce sexual dysfunction.
Dependence on alcohol or marijuana to cope with discomforts of aging may result in weakened erection, reduced desire, or delayed ejaculation.	• Before the patient can decide to stop using alcohol or drugs, the patient must realize the need to change the behavior. The nurse can assist in attitude and value clarification about substance use, sexuality, and sexual behavior. Refer the older adult patient to a counselor who can assist with sexual performance problems as well as emotional and dependence problems.
Age-related metabolic disorders such as anemia, diabetes, malnutrition, and fatigue or depression may affect the quality of life and cause impotence.	• Symptoms may be initially discussed with the nurse. The patient may be hesitant to discuss sexual problems openly. Listen carefully. Acknowledge that sexual problems in the older adult are not unusual. Even if the nurse does not know all the answers, active listening on the nurse's part may encourage the patient to visit a health care provider or a counselor. Encourage older adult patients to have a thorough physical evaluation by a health care provider.
Obesity may damage cardiac and vascular integrity and reduce self-esteem, resulting in decreased sexual performance and interest.	• Encourage the patient to seek the advice of a health care provider and to explore weight reduction and health promotion programs.
Many older adult people are concerned that sexual activity might increase the risk for illness or even death due to stress on the heart or blood pressure.	• Teach the patient that sexual intercourse and similar forms of sexual expression are not considered dangerous for anyone able to walk around a room and may actually offer physiologic benefits. Although there is no risk of pregnancy for females after menopause, both partners need to engage in wellness strategies to prevent STIs.
Radical surgery or dysfunction of the genitourinary tract affects sexual capacity and libido. Extensive surgery due to malignancy may make intercourse difficult or impossible.	• Patients need support and guidance in adjusting to these changes. Provide specific suggestions for how to accommodate to the surgical changes while still maintaining a sexually satisfying relationship. Acknowledge the need for sexual expression in some form or another and provide an open, nonjudgmental response when patients articulate a need for warmth, close contact, and companionship. Touch is particularly important. An atmosphere of trust between the nurse and the older adult patient is essential.
Loss of a spouse or committed partner	• Explore alternative forms of sexual expression with patients who lose their primary sexual partner. Encourage them to attend a support group and become active socially. Acknowledge that human sexuality crosses a wide spectrum and that the pattern for each person is an outcome of their development, experiences, and sense of personal

identity. The basic pattern is not altered by age or loss of a spouse or committed partner. It continues to influence one's capacity for involvement in all life activities.

Source: Adapted from Edelman, C. L., & Kudzma, E. C. (2022). Health promotion throughout the life span (10th ed.). Elsevier; Murray, R. B., Zentner, J. P., & Yakimo, R. (2009). Health promotion strategies through the life span (8th ed.). Prentice Hall, Inc./Pearson Education.

- *Victim of Sexual Assault* and subsequent *Effective Recovery from Sexual Assault*: Problem identification of this nature is very patient-specific and may involve the interprofessional team, law enforcement, and specific counseling. Progression to effective recovery is rarely linear, and is based on existing and developed coping mechanisms and resources.

Before a sexual-based issue is identified as a problem, carefully review the assessment data to determine whether the situation can be corrected by independent nursing interventions. Although many problems of sexuality experienced by a patient in a health care situation are amenable to nursing action, some require the expertise of other specialties.

A patient with impotence and diabetes who would benefit from a penile implant—such as **Jefferson Smith,** described at the beginning of the chapter—needs medical consultation. A patient with a serious sexual dysfunction or one who practices destructive sexual expression needs intensive therapy by a clinical psychologist, sex therapist, or counselor. Appropriate referrals by the nurse should follow the identification of such problems.

Sexual patterns can be further specified by loss of desire (to abstinence), increased desire (to promiscuity), or change in sexual expression. Common etiologies for a change in sexual behaviors include stress (lifestyle, job, family, finances, marital conflict), isolation from partner, effects of pregnancy, feelings of depression, loss of privacy, loss of communication with partner, relationship change (new partner), effects of disease process (sexual position, frequency, mode of expression), change in body image, change in self-concept, or loss of partner.

Sexual function issues may include erectile failure (impotence), premature ejaculation, delayed ejaculation, inhibited sexual desire, orgasmic dysfunction, vaginismus, or dyspareunia. Common etiologies for sexual dysfunction include effects of medication, effects of alcohol consumption, effects of disease process, history of abuse, feelings of depression, guilt, anxiety, fear of rejection, miscommunication with partner, fear of pain, effects of birth control method, lack of knowledge, or effects of surgical procedure.

Changes in sexuality can affect other areas of human functioning. Sexual functioning and expression may be a primary problem for a patient. Examples of these patient problems and needs with related etiology and signs and symptoms can be found in the box titled Examples of Actual or Potential Health Problems and Needs: Patient Experiencing Sexual Alterations or Dysfunction. In the following examples, problems of sexuality are the etiology of another problem (ICN, 2019):

Examples of Actual or Potential Health Problems and Needs

PATIENT EXPERIENCING SEXUAL ALTERATIONS OR DYSFUNCTION

Actual or Potential Health Problems and Needs	Possible Etiologic Factors	Potential Signs and Symptoms
Problematic Sexual Behavior	• Sexual behavior that does not match developmental or expressed comfort level • Lack of exposure, lack of knowledge, or lack of experience	• Verbalizations of feeling pressured to engage in sexual activities with a partner that cause unwanted pain or discomfort • Engagement in vaginal, anal, or

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

		oral sex without a condom to prevent the spread of STIs
Impaired Sexual Functioning	• Underlying medical issue(s) • Medications known to cause sexual dysfunction • History of trauma or abuse • Change in libido—may be physical and/or psychological	• Change in sexual performance that is unacceptable to the person • Inability to engage in wanted, meaningful sexual encounters • Loss of/decrease in sexual desire and drive

Source: International Council of Nurses (ICN). (2019). Nursing diagnosis and outcome statements. https://www.icn.ch/sites/default/files/inline-files/ICNP2019-DC.pdf

- Anxiety related to fear of pregnancy, loss of sexual functioning or desire, or effects of disease process on sexual functioning
- Difficulty Coping related to effects of body image on sexual expression or change in sexual partner
- Disturbed Body Image (specify: surgical excision of genital body part, loss of or gain in body weight) related to fear of rejection
- Disturbed Personal Identity related to alteration in social role, cultural incongruence, discrimination, or stages of growth
- Fear related to pain during sexual intercourse or history of sexual abuse
- Grief related to loss of sexual functioning or effects of surgical excision of genital body part
- Impaired Human Development related to sexual exploitation or abuse, sexual guilt, effects of hormonal imbalance, or lack of information about sexuality
- Lack of Knowledge (specify: contraceptive methods, spread of STIs, sexual response, genital anatomy, modes of sexual expression, self-examination, effects of disease or medications) related to misinformation, sexual myths, lack of interest in learning, or cognitive limitation
- Pain related to sexual position, penile penetration, effects of genital surgery, or lack of vaginal lubrication
- Social Isolation related to effects of marital separation or divorce

Outcome Identification and Planning

Nurses should value sexuality as an important component of who the patient is and how the patient identifies as a unique human. Specific patient outcomes to promote sexual health are identified below.

The patient will:

- Define individual sexuality
- Establish open patterns of communication with significant others
- Develop self-awareness and body awareness
- Describe responsible sexual health self-care practices, identifying appropriate resources
- Practice responsible sexual expression (e.g., by 5/1/25, the patient will use condoms during all sexual encounters)

Specific patient outcomes depend on the nature of the patient's problem or concern. Expected outcomes should be patient-oriented—that is, something the patient desires to do or has the ability to accomplish. For example, it is not enough to advise a method of birth control; rather, the nurse needs to know which method the patient is motivated and able to use.

Implementing

Establishing a Trusting Nurse–Patient Relationship

It is impossible to address a patient's sexuality if trust has not been developed between you and the patient (see Through the Eyes of a Student on page 1884). To develop trust, project an objective, nonthreatening, and nonjudgmental attitude, and emphasize that the information the patient gives will be kept confidential. You need to be aware of your own behavior and verbal and nonverbal cues. You also need to anticipate the patient's concerns to help the patient trust you with information of an intimate nature. Be sure to establish respect for the patient and empathy before discussing sexual issues. Consider all of the patient's circumstances and life experiences using a therapeutic approach. Only when you are accepted as a trusted, caring person will the patient reveal details of their private life, including sexual concerns.

Through the Eyes of a Student

I knew it was going to happen sooner or later, but I admit that I was glad this happened my first clinical rotation with Miss Ethel. Male nurses are not unheard of in this day and age, but some people just aren't yet ready for us—especially Miss Ethel, an 88-year-old woman with a deep religious conviction. I concluded this because she called on Jesus for help when I told her that I was her student nurse for the day, and that I would be giving her a bath.

"You're my nurse?" she said. "Help me, Jesus…. No, no, you just go on and help somebody else, honey. I've already had my bath," she insisted.

I told her she was mistaken and that I understood her anxiety. I proceeded to exaggerate the truth by saying that I had done this before, when really I had given baths before, but not to an older woman. She thought *she* was having anxiety!

Next, I asked my instructor, Mrs. Anderson, for help. She quickly assessed the situation and tried to reassure Miss Ethel (and me) by vouching for my professional character and abilities, but Miss Ethel still was unconvinced. Then I tried using logic with Miss Ethel.

"This is a hospital where male doctors examine you all the time. Why is this any different?" I asked. "Because you are not a doctor," was her logical reply.

I felt inadequate. I could not give this woman the care she needed because of my gender. Luckily, in the next bed, Michele was about to give her patient a bath. Michele offered to give Miss Ethel a bath if I would help her with her patient.

Consequently, Miss Ethel got her bath, and I learned that a nurse has to be flexible as well as willing to ask for and accept help when the patient's quality of care is at stake. Changing assignments is not always possible, but we were able to make it work and honor the patient's request. This is something I hope to remember throughout my nursing career. The good news is that because I maintained a positive attitude and respected her wishes, Miss Ethel and I worked together the rest of the day. I was able to provide detailed teaching and form a rapport with her. Although she was not comfortable with being exposed in front of me, I was able to provide effective nursing care in other ways.

—Daniel E. Zirolli

Delaware County Community College, Media, Pennsylvania

Review the Reflective Practice display for this chapter. Note how the nursing student initially avoided interpersonal contact with **Paul Rojas**, performing the technical aspects of care, but ignoring Paul (the patient) as a person. Communication and trust did not occur until Paul asked the nursing student about her level of discomfort and the nursing student responded truthfully.

Teaching About Sexuality and Sexual Health

Most nursing interventions pertaining to a patient's sexuality involve teaching to promote sexual health. Major goals of patient teaching involve effecting change in knowledge, attitude, or behavior. In some situations, patients need help defining or redefining their sexuality and its importance to their lives. Offering information, dispelling fears, and providing positive reinforcement are some ways to help patients increase their knowledge about their bodies and sexual functioning. Patients may need assistance in modifying behaviors or learning new skills to increase the quality of sexual health and functioning. See the Promoting Health Literacy box.

Promoting Health Literacy

IN PATIENTS RECEIVING THE HPV VACCINE

Patient Scenario

Mrs. Smith, mother of 15-year-old Diane Smith, was told by her daughter's high school that all girls must get the HPV vaccine. Mrs. Smith knows that Diane has been dating a boy from school for almost a year but insists that her daughter "is not sexually active and should not have to get the vaccine." She is

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

primarily concerned that this new vaccine is not safe.

Nursing Considerations: *Tips for Improving Health Literacy*

Tell Mrs. Smith that one in four young females between ages 14 and 19 years is infected with at least one of the most common STIs, which include HPV. According to the Centers for Disease Control and Prevention (CDC), adolescents between ages 11 and 26 years should receive the HPV vaccine.[a] Give both Mrs. Smith and her daughter an information sheet about HPV and the HPV vaccine. Encourage the mother and daughter to be prepared to ask the clinician these questions:

- What problem is the HPV vaccine trying to prevent?
- What do I need to know in order to make an informed decision about getting the vaccine?
- Why does the school think it is important for all girls to get the vaccine?

What additional measures can you take to help increase health literacy in this mother and daughter? What other measures would be helpful if they did not speak English, could not read, or had other learning deficits? What other measures could you take if the daughter confided in you that she is sexually active? What additional measure would be necessary if the primary reason for refusing the HPV vaccine was religious?

[a]Centers for Disease Control and Prevention (CDC). (2020a, March 17). *HPV vaccine recommendations*. https://www.cdc.gov/vaccines/vpd/hpv/hcp/recommendations.html

Part of teaching also includes correcting sexual myths and promoting body awareness. Many people believe things about sex that they have heard from family or friends that are not true or are not based on scientific data. During the assessment, or while providing care, take the opportunity to refute sexual myths and teach factual information (Table 46-4).

Table 46-4 Sexual Myths and Facts to Refute Them

SEXUAL DYSFUNCTION	ASSESSMENT PRIORITIES
Each person is born with a certain amount of sexual drive, which if overdrawn in youth, leaves little reserve for later years.	Actually, the correlation between sexual activity and length of time it persists throughout life is just the opposite. The more consistently sexually active a person is, the longer the activity continues into the later years of life.
A person's need for sexual expression becomes less important in the latter half of life.	Physiologically, sexual desire and ability do not decrease markedly after middle age. The expression of sexuality as an integral part of development follows the overall pattern of health and physical performance.
Sexual abstinence is necessary in training for sports.	Physiologically, the achievement of orgasm is rarely more demanding than most activities encountered in daily life. The desire for sleep that often follows is most commonly due to factors other than physical exhaustion from sexual activities. There is no scientific evidence that sex weakens a person.
Excessive sexual activity can lead to mental illness.	The biological significance of human sexuality has no greater effect on total development than any other necessary biological function. There is no scientific basis for believing that a person will develop a mental or physical illness with excessive or no sexual activity.
Wet dreams are indicators of sexual disorders.	Erotic dreams that culminate in orgasms are normal and common physiologic phenomena in at least 85% of males. They can occur at any age after puberty. Some females also report in clinical studies that their sexual dreams culminate in orgasm. In females, this phenomenon is believed to increase with advancing age.
Because of the anatomical nature of the sex organs, females are passive and males are aggressive.	Physiologic studies disprove this myth by showing females to be far from passive. Sexual satisfaction requires each partner to be both passive and aggressive while participating mutually and cooperatively.
It is unnatural for a woman to have as strong a desire for	These myths have been reinforced by a society that has traditionally taught women that they are to suppress sexual desires to gain love,

sex as a man. Women should not enjoy sex as much as men.	security, and social respect, based on the assumption that it is the basic nature of women to be submissive, dependent, and subordinate. Physiologic studies indicate that, in some respects, a woman's sex drive is not only as strong, but may be even stronger than that of a man.
Women who have multiple orgasms or who readily come to climax are nymphomaniacs or promiscuous.	Physiologic studies suggest that we do not know women's sexual potential; these studies indicate that there is a wide range of intensity and duration of orgasmic experience, and the potential for multiple or frequent orgasms within a brief period is not at all uncommon. Therefore, women normally may have greater orgasmic capacity than men with regard to duration and frequency of orgasm.
There is a difference between vaginal orgasm and clitoral orgasm.	Physiologic misunderstanding has produced the myth of separate clitoral and vaginal orgasms rather than their interrelations. Female orgasm is normally initiated by clitoral stimulation, but because orgasm is a total body response, there are marked variations in intensity and timing. There is no reason to believe that the female response to the sex act is due to a vaginal rather than a clitoral orgasm.
A mature sexual relationship requires both partners to achieve simultaneous orgasm.	Although simultaneous orgasm may be desirable, it is unrealistic. Often, it is possible only under the most ideal circumstances and is not a determinant of sexual achievement or of satisfaction (except to someone who accepts this as dogma).
The larger penis has greater possibilities for producing orgasm in a partner.	Physiologically, there is practically no relation between the size of a man's penis and their ability to satisfy a partner sexually. Furthermore, there is little correlation between penile or body size and sexual potency.
The face-to-face coital position is the proper, moral, and healthy one.	Knowledge of human sexual practices dispels this myth with the recognition that there is no normal or single most acceptable sexual position. Whatever position offers the most pleasure and is acceptable to both partners is correct for them. Any variation is normal, healthy, and proper if it satisfies both partners.
The ability to achieve orgasm is an indicator of a person's sexual responsiveness.	Achievement of a satisfactory sexual response is the result of numerous physical, psychological, and cultural influences. Too often, the physical fact of orgasm (or lack of orgasm) is taken to be symbolic of sexual responsiveness and seen out of context of the entire relationship.

Patients may need assistance in becoming familiar with what they believe and feel about their sexual selves. Be helpful to patients who have difficulty accepting or developing their sexuality by promoting their self-confidence and a positive self-concept. When patients feel comfortable about themselves and their sensual feelings, they can begin to focus on how they feel about their sexual functioning and specific sexual expressions.

Getting to know your physical body is important to healthy sexual development. All people, sexually active or not, need to be aware of the appearance of their genitalia. Some people, because of their background, feel ashamed and repulsed by their bodies; others feel that touching the body is dirty and may feel guilt and anxiety in stimulating themselves. Patients need assistance in improving body awareness if any of these issues are present. Patients can become accustomed to looking at their bodies by looking at nonthreatening anatomy first and then proceeding to the genitals. This can be done in the shower or with the use of a mirror. Knowing what looks normal can be of great importance so that patients can report the development of an unusual appearance later.

After patients have developed some degree of comfort in looking at their bodies, they can progress to experiencing touch. Again, patients should progress from nonthreatening parts of the body until the genitals can be touched without stress.

A good exercise for anyone with a vagina in developing body awareness is the use of Kegel exercises. These exercises promote good vaginal tone by localizing and strengthening the pubococcygeal muscle. A person can locate this muscle by stopping a stream of urine midway through urination. Contracting this muscle can be repeated at any time of the day in any circumstance because its performance is undetectable. Some women who practice Kegel exercises have found that their sexual satisfaction is improved.

Promoting Responsible Sexual Expression

Patients need to know how to gain satisfactory sexual experiences while behaving responsibly in their activities. Responsible sexuality encompasses sexual expression, prevention of unwanted pregnancy, prevention of STIs, and sex

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

education.

Box 46-1 What Can You Do to Prevent STIs?

The best way to prevent STIs is to avoid sexual contact with others. If you decide to be sexually active, there are things that you can do to reduce your risk of developing an STI.

- Have a mutually monogamous sexual relationship with an uninfected partner.
- Correctly and consistently use a male condom.
- Use clean needles if injecting intravenous drugs.
- Prevent and control other STIs to decrease susceptibility to HIV infection and to reduce your infectiousness if you are HIV infected.
- Delay having sexual relations as long as possible. The younger people are when having sex for the first time, the more susceptible they become to developing an STI. The risk of acquiring an STI also increases with the number of partners over a lifetime.

Anyone who is sexually active should:

- Have regular checkups for STIs even in the absence of symptoms, and especially if having sex with a new partner. These tests can be done during a routine visit to the provider's office.
- Learn the common symptoms of STIs. Seek medical help immediately if any suspicious symptoms develop, even if they are mild.
- Use a male condom if practicing anal intercourse.
- Avoid douching because it removes some of the normal protective bacteria in the vagina and increases the risk of getting some STIs.

Anyone diagnosed as having an STI should:

- Be treated to reduce the risk of transmitting an STI to a sex partner or from birthing person to baby.
- Discuss with a doctor the possible risk of transmission in breast milk and whether commercial formula should be substituted.
- Notify all recent sex partners and urge them to get a checkup.
- Follow the provider's orders and complete the full course of medication prescribed. A follow-up test to ensure that the infection has been cured is often an important step in treatment.
- Avoid all sexual activity while being treated for an STI.

Sometimes people are too embarrassed or frightened to ask for help or information. Most STIs are readily treated. The earlier a person seeks treatment and warns sex partners about the disease, the less likely the disease will do irreparable physical damage, be spread to others, or, in the case of a female, be passed on to a newborn baby.

FORM OF SEXUAL EXPRESSION

The form of sexual expression used by patients should not inflict unwanted harm on themselves or others. When sexual expression encroaches on the rights of others, it is neither healthy nor desirable. Sexual acts that violate another's rights are usually considered to be acts of aggression or hostility rather than stemming from sexual need or desire. Rape, in particular, is motivated by a need to dominate and humiliate the victim—it is an act of violence.

PREVENTION OF UNWANTED PREGNANCY

Contraception is a process or technique for preventing pregnancy by means of a medication, device, or method that blocks or alters one or more of the processes of reproduction in such a way that sexual intercourse can occur without impregnation. The prevention of unwanted pregnancy must be a conscious decision. Anyone who is unprepared for pregnancy should refrain from intercourse or obtain a contraceptive method from a health care provider or from the pharmacy; it is too late to think about contraception during sexual intercourse. To practice responsible sex, the contraceptive method must be used consistently and according to instructions.

Prevention of STIs

As described earlier, STIs are widespread. The only sure way to avoid an STI is to avoid all types of intimate genital contact. When this is impractical, there are other practices that can decrease a patient's risk for STIs (Box 46-1). In the United States, Black/African American people account for 42% of new HIV diagnoses in 2018. Black women account for most new cases of HIV and AIDS among women, and are second only to Black, White, and Hispanic/Latino MSM (CDC, 2021d). Most Black/African American women acquire the disease from heterosexual contact, often from a partner who has undisclosed risk factors for HIV infection. A combination of testing, education, socioeconomic support, and behavioral interventions can help reduce the rate of HIV infection and its complications among women of

color.

SEX EDUCATION

Sex education is critical to healthy sexual development and safe sexual behaviors. Information received from peers and friends is almost always inadequate and may be erroneous. Parents/caregivers should be taught to answer children's questions immediately and accurately. Evidence-based, age-appropriate teen pregnancy programs are funded by Congress through Teen Pregnancy Prevention (TPP) Program grants (Office of the Assistant Secretary for Health, U.S. Department of Health & Human Services, n.d.). Abstinence-only programs that do not include more comprehensive approaches have limited (if any) impact on reducing sexual activity. Abstinence-only programs do not influence the number of sexual partners, use of contraceptives, incidence of STIs, or even pregnancy rates. Comprehensive sex education programs improve knowledge, change attitudes and behaviors, and affect outcomes; abstinence-only programs have not been shown to have this positive effect (Chin et al., 2012; Denford et al., 2017; Russell et al., 2020).

Considering Contraception

Unintended pregnancy remains a significant women's health issue in the United States as well as a critical social issue. Healthy People 2020 (2021a) and Healthy People 2030 (n.d.a) aim to improve pregnancy planning and spacing, and to prevent unintended pregnancy, especially in adolescents. Many unintended pregnancies result from the use of less effective methods of contraception, such as condoms, spermicide, or barrier methods. The past several years have seen the development of new, easier to use, and more effective methods of contraception. Nurses and nurse practitioners have a responsibility to provide information to individuals regarding their many contraceptive options (Fig. 46-4 on page 1888).

Patients choose contraception for many reasons and may contact health care providers specifically to obtain information about birth control. Some people use contraception for the orderly spacing of pregnancies in a family; others may want to prevent pregnancy from occurring until a family is desired. Some people choose a permanent method to prevent pregnancy from ever occurring. Factors that affect a person's choice of a contraceptive method include age, marital status, desire for future pregnancy, religious beliefs, level of education, cost, and ease of use. Other considerations include knowledge about available methods, perceptions of various methods, and in many cases, previous experience with contraception.

All contraceptive methods have advantages and disadvantages. Understanding and explaining the available methods thoroughly is a must so that patients can choose the one that will best meet their situation and needs (Box 46-2).

When choosing a contraceptive method, the patient should consider the following:

- How well will it fit into my lifestyle?
- How convenient will it be?
- How effective will it be?
- How safe will it be?
- How affordable will it be?
- How reversible will it be?
- Will it protect against STIs?

Box 46-2 **Knowledge Deficit: Contraceptive Methods**

Assessment Priorities

- Determine the patient's past use of contraceptive methods.
- Assess the effectiveness and satisfaction with past methods.
- Assess the patient's current knowledge of contraceptive methods.
- Assess the frequency of the patient's sexual activity.
- Identify any methods that are unacceptable to the patient.
- Assess the motivation of the patient to use certain methods.
- Assess the patient's level of comfort with manipulation of genital body parts.
- Obtain a complete patient history and perform a physical examination, if indicated.

Expected Outcomes

The patient will achieve the following:

- Choose a contraceptive method that the patient is motivated to use.
- List the adverse effects or danger signs associated with the contraceptive method.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- List the steps needed to use the contraceptive method effectively.
- Use the contraceptive with every act of sexual intercourse.
- Choose a backup method.
- Report back to the health care setting for follow-up as directed.

Nursing Interventions

- Describe in terms at the patient's level of understanding, each contraceptive method for which the patient needs information (give objective information in a matter-of-fact manner to avoid bias by nurse).
- Describe the effectiveness of each method and side effects or possible complications.
- Instruct the patient in the use of a chosen method, giving step-by-step instructions.
- Advise the patient of the importance of having a backup method on hand.
- Instruct the patient in the use of the backup method.
- Have the patient obtain a physical examination if required for the chosen contraceptive method (e.g., the pill).
- Instruct the patient to report back in a specified period for follow-up if indicated (follow-up visits to a health care facility are important, particularly if a patient elects to use oral contraceptives).

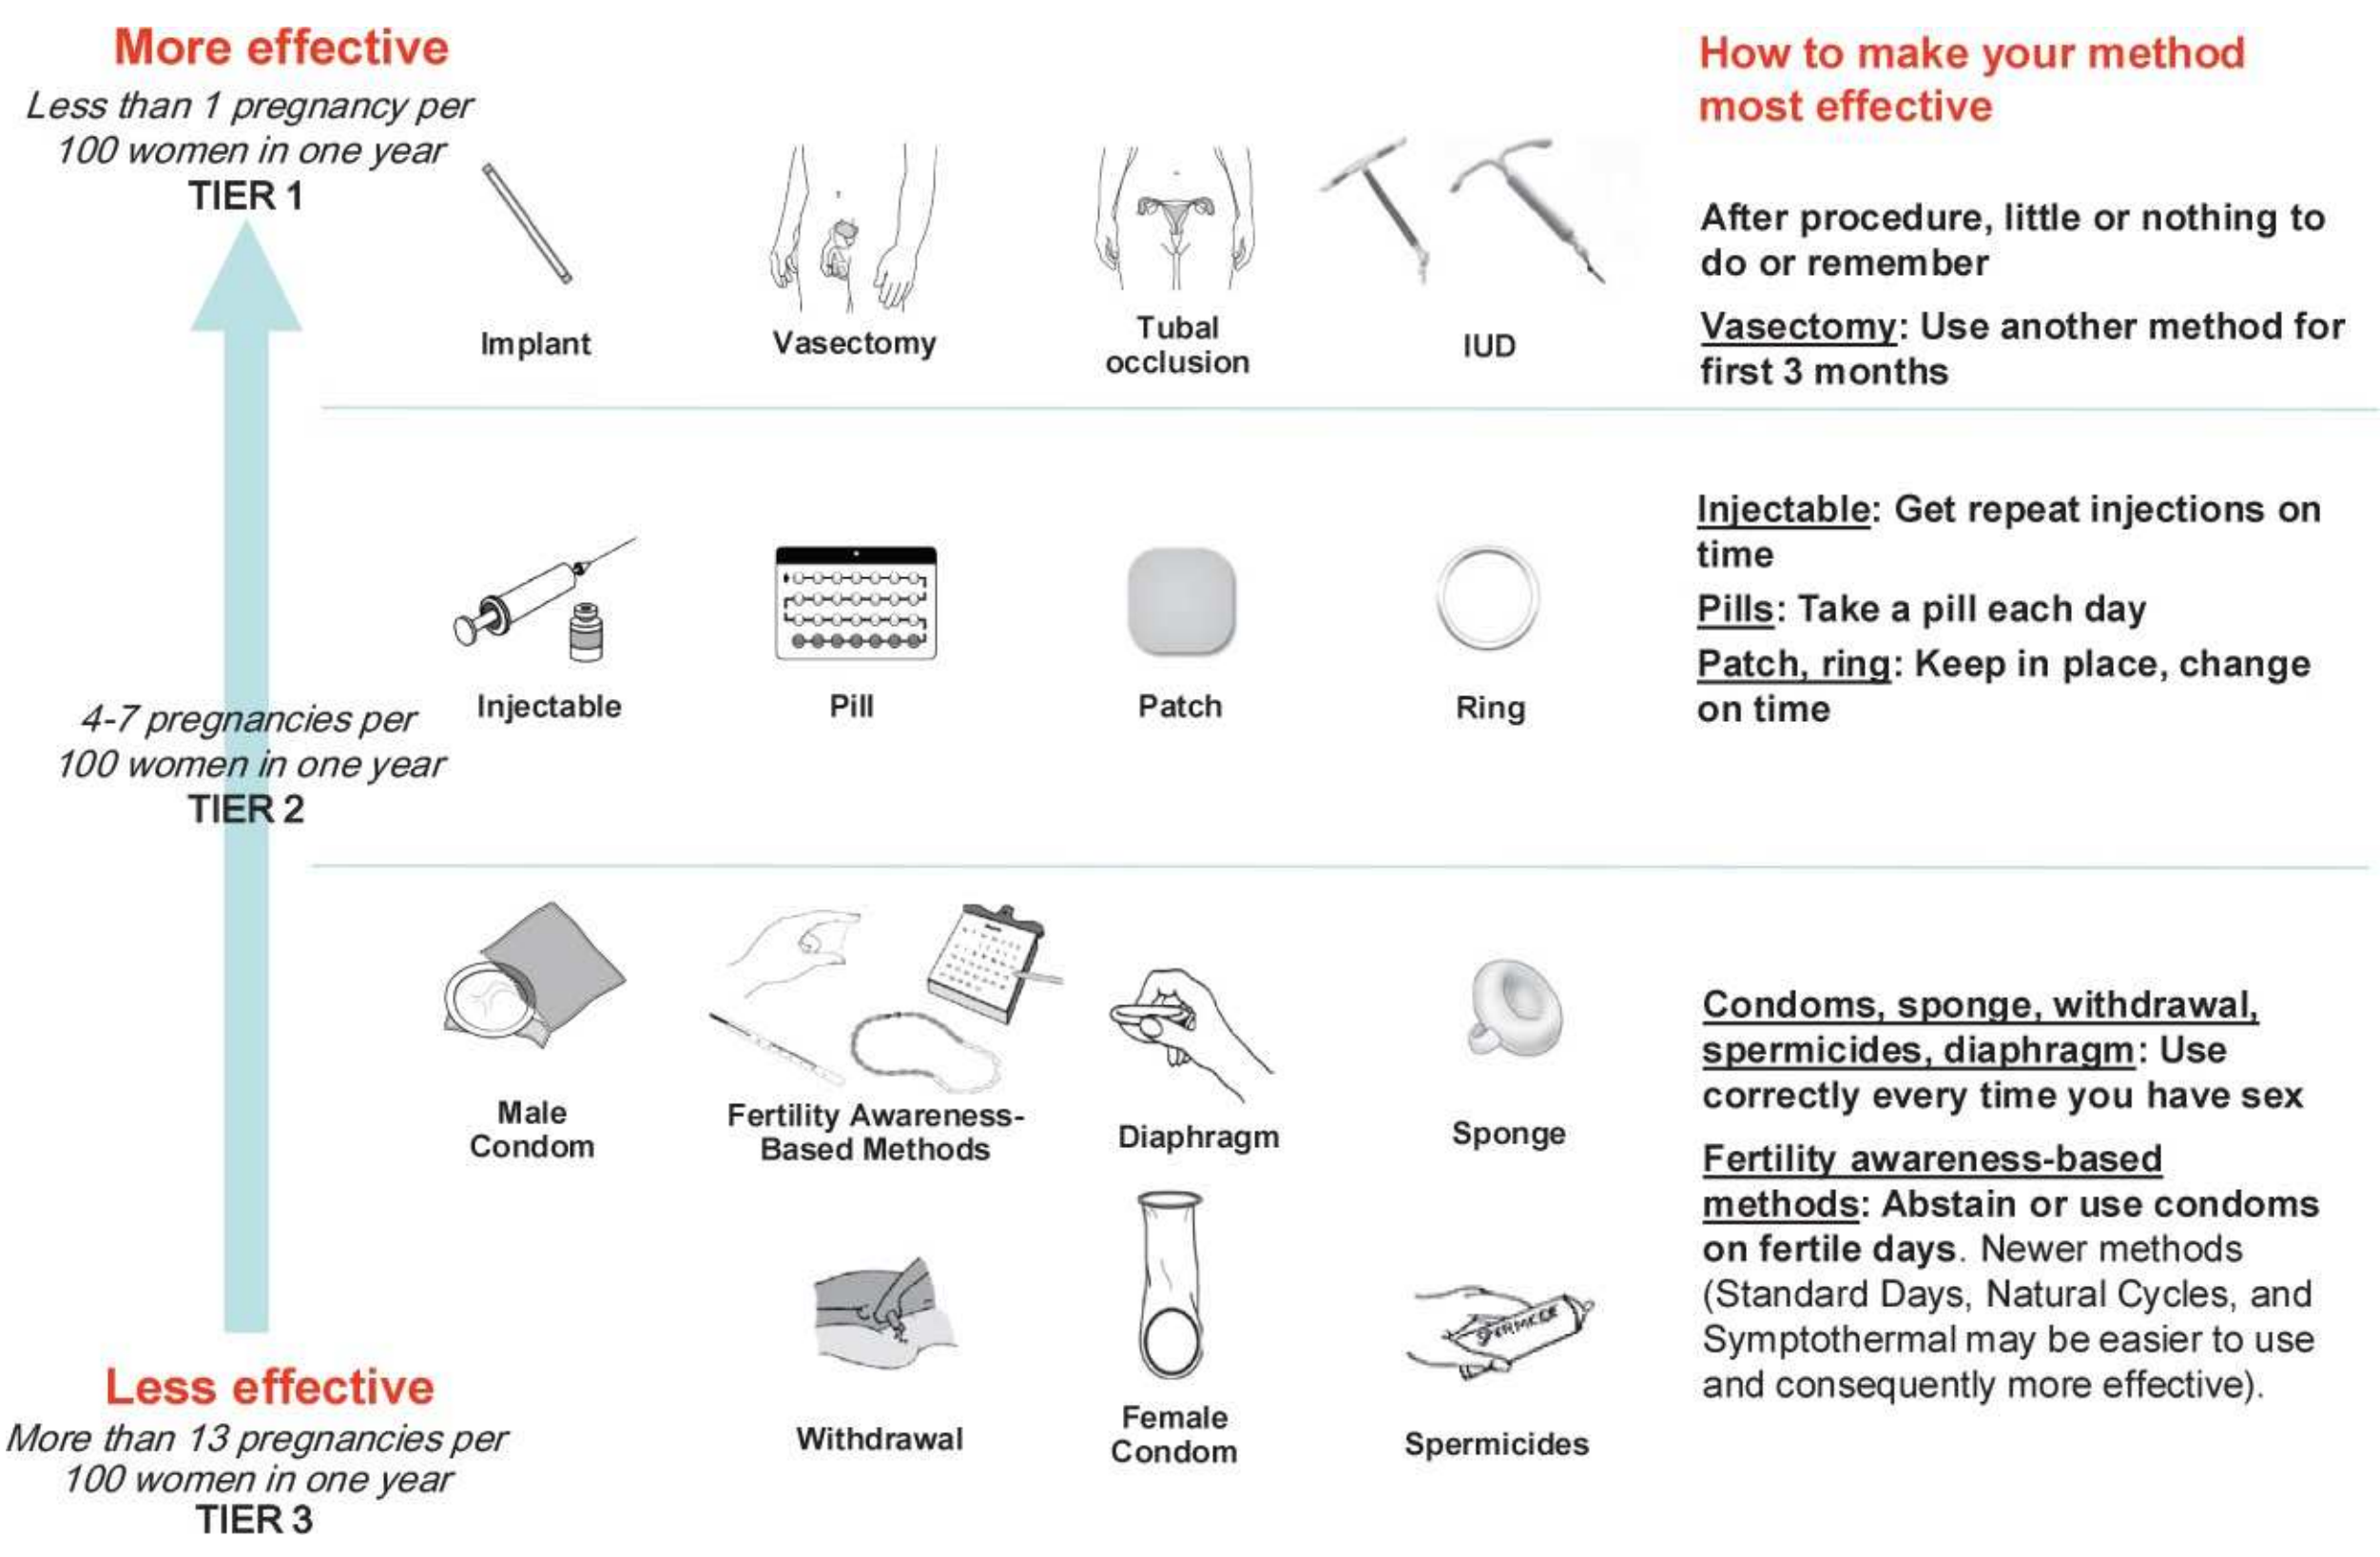

FIGURE 46-4. Contraceptive effectiveness. (*Source*: Trussell, J., Aiken, A. R. A., Micks, E., & Guthrie, K. A. [2018]. Efficacy, safety, and personal considerations. In: Hatcher, R. A., et al. [Eds.], Contraceptive technology [21st ed.]. Ayer Company Publishers, Inc. https://www.cdc.gov/reproductivehealth/contraception/index.htm#Contraceptive-Effectiveness)

BEHAVIORAL METHODS

Abstinence is a behavioral method of contraception. There are two types of abstinence: continuous and periodic.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Choosing abstinence does not mean that a person is sexless. Most people are abstinent at some point in their lives. Abstinence can be a positive way of dealing with sexuality when it represents a well-thought-out decision regarding the person's mind, body, spirit, and sexual health.

Continuous abstinence involves not having any sex with a partner at all. It is 100% effective in preventing pregnancy and STIs. However, people may find it difficult to abstain for long periods of time. Ending abstinence without first being prepared to protect against an unplanned pregnancy or infection may cause additional problems.

Periodic abstinence and fertility awareness methods (FAMs) are two methods of contraception that involve charting a female's fertility pattern. Periodic abstinence is a method used by some sexually active people to prevent pregnancy. They become familiar with their fertility patterns and abstain from vaginal intercourse on the days they think they could become pregnant. Those who monitor their fertility to prevent pregnancy either abstain from vaginal intercourse for at least one third of each menstrual cycle or use barrier methods during the fertile or unsafe period.

Three basic charting methods can be used to predict ovulation to plan or prevent pregnancy (Planned Parenthood Federation of America Inc., 2021):

- *Temperature method:* The female takes her temperature every morning before getting out of bed. The temperature will rise between 0.4°F and 0.8°F on the day of ovulation and will remain at that level until the next period.
- *Cervical mucus method:* The female observes the changes in the cervical mucus throughout the first part of the menstrual cycle, until after ovulation. Cervical mucus is normally cloudy, but a few days before ovulation it becomes clear and slippery and can be stretched between the fingers. This indicates the most fertile phase of the cycle. The couple must abstain from vaginal intercourse or use a barrier method during this period to avoid pregnancy.
- *Calendar method:* The menstrual cycle is charted on a calendar. The couple must refrain from intercourse or use a barrier method during days when pregnancy is more likely.

The best approach to monitoring fertility is a combination of all three methods, called the symptothermal method. FAMs are 76% to 88% effective (Planned Parenthood Federation of America Inc., 2021). Using the methods carefully and consistently, and avoiding unprotected vaginal intercourse during the fertile phase can give better results.

Coitus interruptus, the withdrawal of the penis from the vagina before ejaculation, is one of the oldest and most widely used contraceptive methods. Pregnancy cannot occur if sperm are kept out of the vagina. Although the withdrawal or *pull-out* method is 78% effective if timed correctly, it does not protect against STIs (Planned Parenthood Federation of America Inc., 2021). Preejaculate can contain enough sperm to cause a pregnancy, and preejaculate or semen may spill onto the vulva.

BARRIER METHODS

Barrier methods include the condom, diaphragm, cervical cap, and vaginal sponge used in combination with a spermicidal agent (Planned Parenthood Federation of America Inc., 2021). Cost and the commitment to adhere to a specific regimen affect the choice and efficacy of each option.

Diaphragm

Diaphragm approaches have been used in various forms since ancient times. The current diaphragm is a dome-shaped device made of latex rubber that mechanically prevents semen from coming into contact with the cervix. It is also used to hold a spermicidal jelly in place against the cervix. The diaphragm is placed in the vagina before sexual activity. It fits between the pelvic notch at the front of the vagina to behind the cervix at the back. It is not felt by either partner when correctly situated in the vagina.

A diaphragm must be individually sized during a pelvic examination. Placement and removal of a diaphragm requires a familiarity with the genitals and a level of comfort touching and manipulating the vulva and vagina. The diaphragm must be worn during each episode of sexual activity and consistently used with a spermicidal agent. If used perfectly, a diaphragm is 94% effective; in most real-life situations, a diaphragm is 88% effective (Planned Parenthood Federation of America Inc., 2021).

Condom

The traditional condom is applied to a penis, but it is not unusual for a partner not wearing the condom to have one available. The condom is rolled over the erect penis and collects the semen after ejaculation occurs. If the condom does not have a nipple receptacle end, a small space should be left at the end of the condom to collect sperm (this prevents breakage). Condoms are available over the counter and have become more widely used because of the incidence of HIV/AIDS and other STIs.

A female condom, often called an internal condom, is also available. The female condom is a ringed pouch that unrolls in the vagina. Advantages include the fact that the male does not need to first have an erection for the pouch to be used, and it offers significant protection from STIs.

If used perfectly, condoms are 98% effective at preventing pregnancy; in most real-life situations, condoms are 85% effective at preventing pregnancy (Planned Parenthood Federation of America Inc., 2021). The latex condom

protects against STIs, including HIV. The latex condom offers better protection against STIs than any other birth control method because it blocks the exchange of body fluids that may be infected.

Cervical Cap

The cervical cap is a thimble-shaped rubber device that is placed over the cervix and may be left there for up to 3 days at a time. Its mechanism of action is similar to that of the diaphragm. Not all females can wear a cervical cap because of individual anatomic differences. There is some evidence to suggest that the cervical cap can cause cervical inflammation and increase the risk for pelvic infection.

Spermicides

Spermicides are used with barrier methods but can also be used alone. Spermicides come in creams, jellies, foams, and suppositories. Although readily available, spermicides are not as effective alone as when combined with another method, such as a diaphragm or a condom.

Vaginal Sponge

The vaginal sponge is a barrier method that contains a spermicide. The sponge acts not only as a barrier between the semen and the cervix but also as a reservoir to hold semen. The vaginal sponge carries some risk of toxic shock syndrome (TSS) and is contraindicated for use in females who have a past history of TSS. Anyone who uses the vaginal sponge must follow package directions carefully and remove the sponge within 24 hours. The vaginal sponge is about as effective as the diaphragm.

HORMONAL METHODS

Hormonal methods are based on the feedback mechanism of hormones of the menstrual cycle. Synthetic estrogens and progestin chemical compounds are used in the form of a pill, shot, or implant to prevent ovulation.

Oral Contraceptives

The birth control pill (*the pill*) is the most common contraceptive method and the most popular method for females in their 20s. Most of the harmful side effects and dangers associated with taking the pill are related to the estrogen component. However, most pills currently available contain a small dose of estrogen. The pill also has many beneficial noncontraceptive effects. It has been shown to protect against the development of breast, ovarian, and endometrial cancer. Taken consistently and as prescribed (at the same time every day), the pill is almost 100% effective in guarding against pregnancy. However, based on insurance and access, the ongoing expense may be cost-prohibitive. A health history and physical examination by a health care provider are necessary to obtain a prescription for oral contraceptives. Some females should not take the pill if they have certain physiologic disorders or diseases. Smoking increases the risks associated with oral contraceptives. Remind those who are taking the pill to take measures to protect themselves from STIs.

Nexplanon

In the Nexaplanon system, a single etonogestrel-containing rod is implanted in the upper arm through the use of a disposable insertion kit. Removal, which should occur at the 3-year mark, requires a small incision and takes about 3 minutes. The single-rod system contains 68 mg of etonogestrel in an ethylene vinyl acetate (EVA) copolymer core surrounded by an EVA membrane. This method of contraceptive is 99% effective (Organon Connect, 2022). The most common reason for discontinuation is weight gain.

Depo-Provera

Depo-Provera is the brand name of a progestin-only hormonal birth control system. It uses depot medroxyprogesterone acetate (DMPA), a hormone similar to progesterone (one of the hormones made by the ovaries that regulates the menstrual cycle). An injection of DMPA in the buttock or arm can prevent pregnancy for 12 to 13 weeks and is 99% effective when taken in the prescribed timeframe and 94% effective for those who are late getting their injections. Protection is immediate if the injection is given within the first 7 days of the start of a period. Irregular bleeding is the most common side effect for females using DMPA (Planned Parenthood Federation of America Inc., 2021).

Transdermal Contraceptive Patch

The transdermal contraceptive patch supplies continuous daily circulating levels of ethinyl estradiol (20 mcg) and norelgestromin (150 mcg). The patch is applied weekly on the same day of each week for 3 weeks, followed by a patch-free week. It may be applied to any of four sites: lower abdomen, upper outer arm, buttock, or back. Because it is applied weekly and does not require daily consideration (like the pill), some people prefer the patch, but they have to consider daily time spent in the water (swimming, soaking) and their use of lotions and powders. When used perfectly, the patch is 99% effective at preventing pregnancy, but only 91% effective with mistakes (Planned Parenthood Federation of America Inc., 2021). This contraceptive method has the same contraindications as oral

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

contraceptives. The most common side effects include breast symptoms, headache, application site reactions, nausea, upper respiratory tract infection, and dysmenorrhea.

Vaginal Ring

The vaginal ring is a soft, flexible, transparent ring made of EVA copolymer. It releases approximately 120 mcg of etonogestrel and 15 mcg of ethinyl estradiol daily. After self-insertion into the vagina, the ring generally stays in place for one menstrual cycle, and then may be either disposed of or reused, depending on the specific ring. It does not need to be fitted, nor does it require particular placement within the vagina. The ring works by inhibiting ovulation in much the same way as oral contraceptives. Used appropriately, the vaginal ring is 99% effective in protecting against pregnancy; real-world application shows it to be 91% in preventing pregnancy (Planned Parenthood Federation of America Inc., 2021). Benefits of the vaginal ring include ease of use, self-insertion, high degree of effectiveness, and low incidence of negative or adverse effects. The most common side effects include headache, vaginal discharge, vaginitis, vaginal discomfort, foreign body sensation, coital problems, and ring expulsion.

INTRAUTERINE DEVICES

The intrauterine device (IUD) is an object that is placed by a physician or nurse practitioner within the uterus to prevent implantation of a fertilized ovum. IUDs are small, T-shaped, flexible plastic devices inserted into the vagina through the cervix (using a speculum) that provide reversible birth control. IUDs are classified as copper IUDs or hormonal IUDs (progestin). IUDs seem to affect the way the sperm or egg moves, making it impossible for the sperm to reach the egg. IUDs that contain copper are more effective for two reasons: the copper affects the behavior of enzymes in the lining of the uterus to prevent implantation and causes the production of increased amounts of prostaglandin. Copper IUDs can be used as emergency contraception within five days of sex without a condom. Both types of IUDs have a filament string that serves two purposes: it allows for easier removal by a clinician, and it assists in verifying placement. IUDs are the best, yet sometime cost-prohibitive, birth control option. They are 99% effective primarily because there is nothing to remember to insert, take, or change for 3 to 12 years (Planned Parenthood Federation of America Inc., 2021).

EMERGENCY CONTRACEPTION METHODS

Emergency contraception, often called the *morning after pill*, is designed to reduce the risk of pregnancy after intercourse (without a condom or other birth control method) that could result in a pregnancy. Emergency contraception is provided in two ways (Planned Parenthood Federation of America Inc., 2021):

1. Emergency contraceptive pills delay ovulation and reduce the risk of pregnancy when taken up to 120 hours after intercourse (ideally within 72 hours). Most are up to 89% effective when taken within 72 hours and can be purchased, by an adult, without a prescription.
2. Insertion of a copper IUD within up to 5 days after intercourse.

STERILIZATION

Sterilization should be regarded as permanent and irreversible in males and females. Although sterilization can sometimes be surgically reversed, the results are not always satisfactory. Sexual desire and ability are unaffected by sterilization.

Sterilization in females is accomplished by surgically severing the fallopian tubes. This procedure, known as tubal ligation, prevents the ovum from traveling down the tube. Tubal ligation is usually performed on an outpatient basis, sometimes under local anesthesia. Postoperative care and recovery time are required after a tubal ligation. Sterilization is safe and, because it lasts for life, is simple and convenient.

Sterilization in males is accomplished by surgically severing the vas deferens, which prevents sperm from entering the semen. The vasectomy is usually performed in a health care provider's office under local anesthesia. Vasectomy is the most effective birth control for males—nearly 100% effective. An alternative form of contraception is necessary until two semen analyses show zero sperm. It usually takes about 4 to 6 weeks for all stored sperm to be eliminated from the ductal system.

FUTURE TRENDS

Private industry remains a driving force behind contraceptive research and development. More than 100 experimental contraceptive methods are being studied around the world. The U.S. government contributes to contraceptive research primarily by funding research conducted at the National Institutes of Health.

About 43% of the pregnancies in the United States are unintended. To decrease the negative effect of unintended pregnancy on the birthing person and the infant, current initiatives center on increasing the use of and access to birth control, providing family planning services, and linking adolescents to targeted health care that may help prevent pregnancy and STIs (Healthy People 2030, n.d.a). Future trends in contraception are likely to be shaped in part by increased awareness of STIs and continuation of the AIDS pandemic.

Female Contraceptives

Most of the contraceptive products that will soon be available are refinements of products already available. New barrier methods will include enhanced cervical caps and vaginal sponges with microbicides to protect against STIs. New contraceptive pills, patches, and rings will use varied combination of hormones. Injectable progestin products may one day protect against pregnancy for up to 90 days. Oral and injectable vaccines may one day immunize females against pregnancy. These vaccines might produce antibodies to attack egg or sperm, or the immune system might create antibodies to a crucial type of protein molecule found on the head of sperm. Contraceptive implants designed to remain effective for 2 or 3 years, as well as biodegradable implants with efficacy of up to 18 months, are in development. Computerized fertility monitors that predict ovulation will offer couples who use FAMs of contraception a much more sophisticated and accurate charting method. Methods for permanent sterilization will expand to include chemical scarring techniques and insertion of fallopian tube chemical plugs and cryosurgery. Temporary sterilization may be achieved by the use of silicone plugs.

Unisex Reversible Contraceptives

The concept of unisex reversible contraception is being explored. This method involves a group of drugs called gonadotropin-releasing hormone (GnRH) agonists and can be used to prevent the release of follicle-stimulating hormone (FSH) and luteinizing hormone (LH) from the pituitary gland. The release of FSH and LH triggers ovulation and spermatogenesis. Blocking the release of these hormones will temporarily suppress fertility for females and males.

Male Contraceptives

Methods of contraception for males continue to be explored. The challenge of developing a reversible method of contraception for males is complicated because they are always producing sperm. Because of this continuous fertility, the opportunities for reversible intervention that are permitted by females' fertility cycles are not available for males. Various contraceptive injections, implants, and vaccines for males are being researched.

Effective contraceptive methods that do not permanently impair fertility have proven elusive, but research continues. Most research has focused on a hormonal approach to decrease spermatogenesis. The major problem is that interference with steroidogenesis may also interfere with the other actions of testosterone such as sexual function, bone and muscle growth, kidney function, and protein anabolism.

Research in Nursing

Bridging the Gap to Evidence-Based Practice

Transphobia

Transgender women experience high rates of gender-based violence (GBV), such as transphobic hate crimes, which can negatively impact their health outcomes. Exploring self-reported experiences with these crimes provides insight into the lived experience of these women.

Related Research

Gyamerah, A. O., Baguso, G., Santiago-Rodriguez, E., Sa'id, A., Arayasirikul, S., Lin, J., Turner, C. M., Taylor, K. D., McFarland, W., Wilson, E. C., & Wesson, P. (2021). Experiences and factors associated with transphobic hate crimes among transgender women in the San Francisco Bay Area: Comparisons across race. *BMC Public Health*, *21*(1), 1053. https://doi.org/10.1186/s12889-021-11107-x

An interprofessional team engaged in a secondary analysis of data collected in a longitudinal cohort study of HIV (n = 629). This analysis focused on self-reported experiences of transphobic hate crimes in the San Francisco Bay area. Demographic and sociocultural factors including race and ethnicity along with gender identity factors were examined in relation to transphobic experiences and whether or not the crime was reported to the police. Not surprisingly, 45.8% of these transgender women reported they had experienced a hate crime, but only 51.1% of those cases were reported to the police. This analysis supports the assertion that these crimes are underreported, especially when the women felt their gender identity was questioned, which makes tracking transphobic hate crimes difficult. Structural factors and social determinants of health including poverty, unemployment, sex work, incarceration, immigration status, housing discrimination, and unhomed status are all associated with trans women's risk for experiencing a hate crime. The intersectionality of race, ethnicity, gender, and transphobia increase the risk of violence for Black and Latina trans women. Although the overall hate crime rate did not show significant differences based on race or ethnicity, Black and Latina transgender women were more likely to experience battery with a weapon than their White counterparts.

Relevance for Nursing Practice

Trans women who have their gender identity questioned in the context of a hate crime are less likely to report the crime. Nurses have an obligation to provide a safe space for women to express themselves and advocate for their individualized needs. Policies that address structural issues related to racial disparities, intersectionality, and other

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

social determinants of health would benefit the trans population directly.

Facilitating Coping With Special Sexual Needs

The nurse can help patients cope with sexual concerns generated by diseases and their treatments. See the accompanying Research in Nursing box. Offer anticipatory guidance and information to patients, stressing the importance of open communication with the patient's partner. Include the partner in teaching when appropriate.

When indicated, start a discussion about possible sexual positions that can reduce pain during coitus. Show the patient drawings of possible sexual positions. Inform the patient that intercourse may be more comfortable if pain medication is taken before beginning sexual activity.

When teaching patients about medications, mention any sexual side effects that may occur to prevent anxiety and depression. Patients should alert the health care provider if these side effects occur because the drug dosage may be able to be modified or the drug changed. If patients are unaware of this, they may discontinue the medication on their own rather than sacrifice sexual functioning, especially if this is an important aspect of life for them.

Health Care Needs of Lesbian, Gay, Bisexual, and Transgender People

The health and well-being of lesbian, gay, bisexual, and transgender (LGBT) people has been made a priority by major federal health care facilities. The term LGBT has been expanded to LGBTQIA+ (lesbian, gay, bisexual, transgender, questioning/queer, intersex, ally/asexual), but the terms associated with the acronym vary slightly depending on the source. The plus sign is often used to include those whose personal identity is not represented by any of the other terms. The Institute of Medicine's consensus report (IOM, 2011; since renamed the National Academy of Sciences, Engineering, and Medicine), Healthy People 2020 (2021b), Healthy People 2030 (n.d.b), and USDHHS (2016) all highlight the need for better science-based knowledge on how best to address the existence of health disparities of the LGBTQIA+ community and the lack of compassionate services. Stigma and a range of other social and cultural factors affect the health of LGBTQIA+ people, as well as the ability of the health care system and providers to care for them. LGBTQIA+ people come from diverse cultural backgrounds, have varied ethnic or racial identity, and differ in terms of education, age, income, and place of residence. LGTBQIA+ may be defined by their sexual orientation, but this definition is complex and variable. Sexual behavior, cultural factors, disclosure of sexual orientation and/or gender identity, prejudice and discrimination, and concealed sexual identity each present unique health challenges to this population (Box 46-3).

Other issues that affect health care delivery to the LGBTQIA+ population include the following:

- *Public health infrastructure:* Efforts to research and address the health care needs of LGBTQIA+ people are hindered by an inadequate infrastructure to support and fund population-specific initiatives.

Box 46-3 Health Disparities in the Gay, Lesbian, Bisexual, and Transgender (LGBT) Population

Healthy People 2020 (2021b) identified significant LGBT health disparities and sought much-needed collaboration from health care professionals and policy makers to address them. Among its findings are the following:

- LGBT youth are two to three times more likely to attempt suicide.
- LGBT youth are more likely to be homeless.
- Lesbians are less likely to get preventive services for cancer.
- Gay men are at higher risk of HIV and other sexually transmitted infections, especially among communities of color.
- Lesbians and bisexual females are more likely to be overweight or obese.
- Transgender people have a high prevalence of HIV and sexually transmitted infections, victimization, mental health issues, and suicide: They are less likely to have health insurance than heterosexual, lesbian, gay, or bisexual people.

Based on the progress on the 2020 initiatives, *Healthy People 2030* (n.d.c) focuses on LGBT adolescents and related school- and family-based interventions to address the specific challenges faced by these adolescents.

- Older LGBT people, referred to as *elders* by the LGBT community and *trans elders* in the transgender community, face additional barriers to health due to isolation and a lack of social services and culturally competent providers.[a]
- LGBT populations have the highest rates of tobacco, alcohol, and other drug use. These health issues are partly thought to be the effects of chronic stress resulting from stigmatization.[b]

[a]Harley, D. A., & Teaster, P. B. (2016). *Handbook of LGBT elders: An interdisciplinary approach to principles, practices, and policies*.

Springer International Publishing.

[b]Institute of Medicine, Committee on Lesbian, Gay, Bisexual, and Transgender Health Issues and Research Gaps and Opportunities. (2011). *The health of lesbian, gay, bisexual, and transgender people: Building a foundation for better understanding*. National Academies Press.

- *Access to quality health services:* Financial, structural, personal, and cultural barriers limit access to screening and prevention services and cause delays in care for acute conditions in the LGBTQIA+ population.
- *Health communication:* Negative provider attitudes, lack of provider education regarding unique aspects of lesbian and gay health, and exclusion of same-sex partners in care planning seriously hamper therapeutic communication between members of the LGBTQIA+ community and those who provide care.
- *Educational and community-based programs:* Some government facilities, professional organizations, and health care organizations address health issues of the LGBTQIA+ community, but this population still relies heavily on self-created community-based programs to address their special health care requirements.

Clearly, significant research is needed regarding the unique experience and health care needs of the LGBTQIA+ population, along with increased education for health care providers. Issues of prejudice and inequitable service distribution in the health care system need to be addressed to improve the health of this population.

Think back to **Paul Rojas,** a young adult man who is gay and was diagnosed with AIDS. The nurse needs to be acutely aware of the health care delivery system in the community to ensure that Mr. Rojas has access to the most appropriate and needed services. Depending on his specific needs, consultation with social services may be helpful for initiating referrals for appropriate services as Mr. Rojas's condition changes.

Advocating for Patients' Sexuality Needs

A hospital experience or institutionalization puts a strain on a person's individuality and sexual self. Illness may diminish feelings of sexual desire, and the desire for sexual interaction can signal a patient's improving health. The nurse should provide anticipatory guidance because many patients may hesitate to request help for fear of being ridiculed. Often, a patient merely desires privacy to hold and caress their partner. The intimacy of this act often fulfills the patient's feelings of longing to be needed and loved.

There are many ways to advocate for a patient's sexual needs (Box 46-4 on page 1894). Some may seem obvious and commonplace, whereas others may first require coming to terms with your own sexuality.

Box 46-4 Advocating for Patients' Sexual Needs

- All patients should be accepted as sexual beings with the right to be treated with dignity and with sensitivity to their feelings.
- All patients have the right to some degree of privacy.
  - Anticipate the patient's desire for privacy by the simple act of drawing a curtain or closing a door.
  - Give patients the option of wearing their own sleepwear to promote sexual identity.
- Anticipate potentially shaming situations for the patient. Give information regarding the procedure and why it needs to be done, and acknowledge that the patient's embarrassment is normal and understandable.
- Health care providers should not simply take for granted that patients do not mind intrusive or embarrassing procedures performed on their bodies and private parts.
- Patients have a right to question the heath care provider regarding sexual needs or future sexual functioning.
  - Anticipate these questions for the patient.
  - Ask patients if they have any concerns regarding sexuality that can be answered by the nurse.
  - Interface with the health care provider to obtain information required by the patient.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

- The atmosphere in health care settings needs to allow for sexual expression between patients and their partners.
- Confidentiality is a right of every patient.
  - Do not promise confidentiality if that promise cannot be kept.
  - Do not allow anyone not directly involved with the patient's care access to a patient's personal records.
  - Allow no information regarding patients to escape into idle conversation.
- Patients should be referred to formally by whatever name or title the identified by the patient. Use appropriate pronouns.
- Patients should be allowed to keep some personal possessions, if it is practical to do so.

Counseling the Patient Regarding Sexuality

Not all patients with sexual concerns need intensive therapy. Some patients benefit greatly from simply having someone listen to their concerns. Voicing their concerns allows patients to put the information into perspective and focus on what the problem is and how to solve it. When counseling patients, do not offer your own advice, because what is right for one person may be wrong for another. Also, offering false reassurances, such as, "It'll be all right," is unproductive. Rather, adopt an objective, nonjudgmental, empathic, and receptive attitude to facilitate open communication with the patient.

Abortion Counseling

Abortion remains an issue that deeply divides people. Many believe it is a woman's right to choose whether to continue a pregnancy or to take safe and legal action on a decision to terminate. Others believe that from fertilization onward, the embryo and fetus is a human being deserving of the full respect and protection we afford humans after birth; these people view abortion as always wrong. Some would allow abortion only if it is indicated for a birthing person's health or in cases of rape. You should examine what you believe, why you believe this, and how your beliefs are likely to influence your ability to counsel individuals and couples of childbearing age.

Counseling in Cases of Abusive Relationships and Rape

Nurses encounter children, adolescents, women, and sometimes men who have experienced sexual abuse or rape. Sexual violence (rape, forced sodomy, sexual child abuse, incest, fondling, sexual harassment, or any unwanted sexual contact) is *not* about love or sex; it is about power, violence, and control. The Rape, Abuse & Incest National Network (RAINN, 2022) reports that:

- One out of every six American women has been a victim of an attempted or completed rape in her lifetime (14.8% completed rape; 2.8% attempted rape).
- About 3% of American men—or 1 in 33—have experienced an attempted or completed rape in their lifetime.
- Every 68 seconds, an American is sexually assaulted.
- Approximately 15% of victims of sexual assault and rape are ages 12 to 17 years; 54% are ages 18 to 34 years.
- The majority of sexual assaults occur at or near the victim's home; 48% of victims were sleeping or at home doing something else when the crime occurred.
- Approximately 21% of transgender college students have been sexually assaulted (compared to 18% of nontransgender females and 4% of nontransgender males).

Date rape occurs when there is forced or coerced sex within a dating relationship. With acquaintance rape, the act is committed by someone known to the victim. Nearly two thirds of all victims between ages 18 and 29 years report that they had a prior relationship with their attacker. More than 13% of college women report they have been forced to have sex while in a dating situation (Center for Family Justice, 2021).

Victims of sexual assault are 3 times more likely to suffer from depression, 6 times more likely to suffer from posttraumatic stress disorder, 13 times more likely to abuse alcohol, 26 times more likely to abuse drugs, and 4 times more likely to contemplate suicide. Clearly, nurses need to be alert to evidence of sexual abuse while taking the history and conducting physical examinations. Abuse crosses all socioeconomic and ethnic groups. Become familiar with your legal and clinical responsibilities when a victim is identified. The first priority is getting the victim into a safe environment and mobilizing support for the victim and family. Multiple parties may need therapy. Be familiar with local resources and make appropriate referrals. The National Sexual Assault Online Hotline is a free, confidential, secure service that provides live help over the RAINN website (https://www.rainn.org/get-help).

Human trafficking is a form of abuse and a human rights violation. Although data collection on human trafficking is difficult to collect, the public is aware of this issue through public service announcements at airports, online, and on television. There is even a TikTok video on a hand signal to alert others: put your hand up with the palm facing out, tuck the thumb, and then trap the thumb with the other four fingers (making a fist with the thumb inside). See the Vulnerable Populations Alert on Human Trafficking for more information.

Evaluating

The nurse works with the patient to evaluate the effectiveness of sexual counseling or intervention. Several factors can be considered when evaluating the sexual health of an individual (Boyd & Luebbert, 2022; Stuart, 2013):

- *Wellness*. Has the patient's sense of well-being improved during the treatment? Have issues regarding access and disparities been addressed?

Vulnerable Population Alert: Human Trafficking Victims

Identifying Victims of Human Trafficking Fact Sheet: https://www.acf.hhs.gov/sites/default/files/orr/fact_sheet_identifying_victims_of_human_trafficking.pdf.

Who Is a Human Trafficking Victim? Human trafficking is a form of modern-day slavery in which victims are subjected to force, fraud, or coercion for the purpose of commercial sex, debt bondage, or involuntary labor. Victims of human trafficking can be young children, teenagers, and adult males and females. They can be U.S. citizens, Lawful Permanent Residents (LPRs), or foreign nationals, and they can be found in urban, suburban, and rural areas. Minors (younger than age 18 years) who are induced to perform commercial sex acts are victims of trafficking, regardless of whether their traffickers used force, fraud, or coercion.

Human trafficking may occur in the following situations:

- Prostitution and escort services;
- Pornography, stripping, or exotic dancing;
- Massage parlors;
- Sexual services publicized on the Internet or in newspapers;
- Agricultural or ranch work;
- Factory work or sweatshops;
- Businesses like hotels, nail salons or home-cleaning services;
- Domestic labor (cleaning, childcare, eldercare, etc. within a home);
- Restaurants, bars, or cantinas; or
- Begging, street peddling, or door-to-door sales.

Victims of human trafficking may exhibit any of the following:

- Evidence of being controlled either physically or psychologically;
- Inability to leave home or place of work;
- Inability to speak for oneself or share one's own information;
- Information is provided by someone accompanying the individual;
- Loss of control of one's own identification documents (ID or passport);
- Have few or no personal possessions;
- Owe a large debt that the individual is unable to pay off; or
- Loss of sense of time or space, not knowing where they are or what city or state they are in.

If you think you have come into contact with a victim of human trafficking, call the National Human Trafficking Resource Center at 1.888.3737.888. The NHTRC can help you identify and coordinate with local organizations that protect and serve trafficking victims. For more information on human trafficking visit: www.acf.hhs.gov/trafficking

- *Functional ability*. If the person was dysfunctional, has functional ability improved or been restored? Have medical and behavioral strategies been implemented?
- *Satisfaction with treatment*. Does the patient believe the treatment was helpful? Were the patient's goals and expectations met? Does the patient feel seen, heard, and supported without bias or discrimination? Has the health care team partnered with the individual to develop a plan?

To evaluate the plan of care, the nurse needs to use information from the patient for most outcomes. The nurse cannot evaluate patients by observing their expression of sexuality, but the nurse can evaluate how patients are progressing toward sexuality-oriented goals by their appearance, self-confidence, and manner. For example, a patient who has expressed feelings of anxiety in the past over a sexual concern should be observably more confident and exhibit less anxiety if the patient outcomes are being met. Ask the patient about progress toward outcomes. Some outcomes need to be incrementally addressed because not all problems are easily resolved with one-time intervention and direction.

When evaluating a patient's progress, it may help to ask these questions: "In what ways have you been able to achieve your goal (orgasm, increased desire, comfortable intercourse, erection)?" "What methods seemed most effective? Which were not?" "What do you think should be the next step?" Determine from this interaction with the

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

patient whether something more needs to be accomplished. It is not enough to assume that because a set of outcomes has been met, the patient is satisfied with the results.

REFLECTIVE PRACTICE LEADING TO PERSONAL LEARNING

Remember that the object of reflective practice is to look at an experience, understand it, and learn from it. As you begin to develop your expertise in evaluating the care plan, reflect on your experiences—successes and failures—in order to improve your practice. How can you do it better next time? What did you learn today that can help you tomorrow? Begin your reflection by paying close attention to the following:

- How aware are you of the components of sexuality: biological sex or sex assigned at birth, sexual activity (including pleasure, intimacy, and reproduction), gender identities and roles, and sexual orientation?
- What value do you attach to sexuality? How will you begin to approach discussing these personal concepts with your patients? How do you individualize the care for patients?
- How do you plan to hone your skills in managing the complexities of sexuality that can involve psychological and physiologic aspects?

Keeping up with the latest evidence-based practice guidelines, evolving terms, public opinion, and legal protections can be challenging. Developing a working knowledge of the core principles of sexuality and identity provides a foundation for your nursing practice.

Perhaps the most important questions to reflect on are : Are your patients and families/caregivers better for having had *you* share in the critical responsibility of partnering with them to explore and embrace their sexuality? Are your patients now receiving thoughtful, person-centered, prioritized, holistic, evidence-based treatment and care because of your efforts?

Nursing Care Plan for Pete Manheim 46-1

Pete Manheim is a 13-year-old adolescent boy attending the area health clinic. His mother consented to the nurse conversing with Pete and agreed to leave the room to provide her son privacy. Pete tells you his pronouns are *he* and *his* and that he identifies as straight. He is nervous as he explains to the nurse his need for health care. He has noticed "sticky white stuff" around his penis and bedclothes on arising some mornings and fears he may be ill. Pete has also expressed concern about his lack of knowledge regarding sexuality. He has heard a lot of stories from his friends but does not feel he can talk to his parents because the subject has never been broached at home. Also, although Pete is "a virgin", he is beginning to feel pressured by his friends, who boast of many sexual experiences.

After spending time in conversation with Pete, the nurse gathered the following data:

- Pete is experiencing nocturnal emissions and has little scientific knowledge about their source.
- Pete is anxious because of the stories regarding sex he has heard from his friends.
- There is no communication or dialogue at home with parents about issues of sexuality.
- Pete is having feelings of insecurity and anxiety about his present virginal status, which he feels he should change.
- Peer pressure from friends is also a concern.

The nurse will work with Pete to develop a care plan to correct misinformation and relieve his anxiety. Planning will be directed toward correcting myths and supplying Pete with accurate information. Because Pete has a negligible knowledge base on sexuality, the care plan will allow for ongoing sessions to augment the initial information. The nurse should outline this plan with Pete to be certain it is acceptable to him.

ACTUAL OR POTENTIAL HEALTH PROBLEMS AND NEEDS

Knowledge Deficit: Adolescent Sexuality Concerns

Etiology: misinformation and absent family-based sex education

Signs and symptoms: the patient's self-report.

EXPECTED OUTCOME

By the end of the teaching session, the patient will:

- Describe the nature of nocturnal emissions

NURSING INTERVENTIONS	RATIONALE	EVALUATIVE STATEMENT
Assess patient's present knowledge base on nocturnal emission and the	It is necessary to discover what the patient does know and to build on	8/1/25 Outcome met. Patient able to describe the source of nocturnal

source of his information.	that knowledge.	emissions. *N. Hill, RN*
Use terms that the patient has used and language at the level of the patient's understanding.	This facilitates comprehension.	
Teach the patient about nocturnal emissions: • Nocturnal emissions, or "wet dreams," are normal in males of all ages, and they are particularly common in the teenage years. They are not the result of disease. • They occur during sleep as the result of erotic dreams. The "white sticky stuff" is the result of ejaculation of semen from the penis. • This is an involuntary action over which the male has no control.	Knowledge decreases anxiety.	

EXPECTED OUTCOME

By the end of the teaching session, the patient will:

- Differentiate sexual myths from sound knowledge

NURSING INTERVENTIONS	RATIONALE	EVALUATIVE STATEMENT
Assess what the patient has heard from peers regarding sexual information:	The nurse can then specifically address the myths to which the patient has been exposed. This enables the patient to develop a positive sexual body image based on fact.	8/1/25 Outcome met. Patient was able to differentiate between truth in sexual issues and what is myth. *N. Hill, RN*
Myth 1: "A large penis is better for sex than a small one." *Truth:* No relation exists between the size of a penis and the male's ability to perform sexually. When a penis becomes erect, it reaches sufficient size to engage in sexual intercourse.		
Myth 2: "Jerking off causes blindness. It is a dirty habit." *Truth:* Masturbation, or self-stimulation, is a natural and healthy outlet for sexual urges. People of all ages masturbate. Masturbation can also teach the person what feels good and what does not. Every person has the right to masturbate if desired.	The patient is given permission to engage in a sexual activity of a masturbatory nature.	
Myth 3: "It looks bad for a guy to be a virgin—everybody's doing it" (having sex). *Truth:* No one, whether male or female, should feel pressured into sexual activity at any age. Engaging in sexual activity carries with it a	The patient is given permission to abstain from sexual activity and not to feel pressured by friends. Almost 39% of teens have had sex by age 16	

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

great deal of responsibility and concerns of pregnancy and spread of sexually transmitted infections (STIs). No one needs to know of another person's status if the person chooses not to discuss it.	years.	

EXPECTED OUTCOME

By the end of the teaching session, the patient will:

- List the positive aspects of abstinence in a sexual relationship

NURSING INTERVENTIONS	RATIONALE	EVALUATIVE STATEMENT
Assess the patient, including previous discussion of sexual myths and knowledge. Instruct the patient on the positive aspects of abstinence, including the following:	Giving the patient all the information necessary allows him to make an informed decision.	8/1/25 Outcome partially met. Patient able to list verbally all positive aspects of abstinence but is still undecided.
• Engagement in any sexual activity should be a personal decision and not the result of pressure from friends.		*Revision:* Reinforce to patient that this is a personal decision that he can make for himself with a good knowledge base. Also, he does not have to make a firm decision for or against abstinence immediately. He should take time to think about this information. *N. Hill, RN*
• Abstinence will guarantee protection from pregnancy and from most STIs.	Many young people think they are immune to the consequences of their actions. Therefore, it is important to stress that pregnancy and STIs are very probable results of sexual intercourse.	
• People can show affection for each other without sexual involvement.	It is difficult to understand and undertake all the implications of a sexual relationship during the teenage years. The patient learns that a successful sexual relationship requires intimacy, love, and sharing; it should not be merely an outlet for sexual feelings.	
• Every person has the right to say no.	The patient has permission to refuse an activity in which he is not sure he wishes to engage.	

EXPECTED OUTCOME

By the end of the teaching session, the patient will:

- Describe the correct use of rubber condoms

NURSING INTERVENTIONS	RATIONALE	EVALUATIVE STATEMENT
Assess what the patient knows about condoms and their use.	Since the patient is undecided about whether to initiate a sexual relationship in the future, it is prudent to give him information to protect against pregnancy and STIs.	8/1/25 Outcome met. Patient successfully listed the steps in using a condom. *N. Hill, RN*

Inform the patient that condoms are available over the counter in drugstores. Prices vary according to type and style.	Patient should know where to purchase condoms and the variety available.
Teach the patient the steps in using rubber condoms:	Patient should know how to use condoms safely.
• Roll condom onto the penis as soon as it becomes erect.	Protects against sperm from secretions from Cowper's glands
• If condom does not have a nipple receptacle end, leave a small space at end of condom to collect semen.	Provides a pocket to collect semen and prevents breakage
• Immediately after ejaculation, remove penis and condom from vagina by holding onto base of condom.	Prevents spillage of semen into the vagina
• Discard condom.	Condoms are not meant to be reused. A new condom is used for each act of intercourse.
Advise the patient to use a condom with every act of intercourse. Spermicides used with the condom increase effectiveness.	To be as effective as possible, the condom should be used with every act of intercourse. The rubber condom used with spermicide is effective against pregnancy and the spread of STIs. The use of a spermicide foam in the vagina increases effectiveness.

EXPECTED OUTCOME

By the end of the teaching session, the patient will:

- Express a decrease in anxiety

NURSING INTERVENTIONS	RATIONALE	EVALUATIVE STATEMENT
Assess the patient's anxiety level by verbal and nonverbal behavior.	The patient was anxious when he came into the clinic. It is important to evaluate his level of anxiety before he leaves. If he is still anxious, reassessment should occur because the care plan may have been unsuccessful.	8/1/25 Outcome met. Patient expressed relief that he is normal. Would like to bring a friend to next session. Future teaching sessions to include these topics identified by patient: • STIs, particularly AIDS • Pregnancy—occurrence and prevention • Sexual expression • Further discussion of sexual myths *N. Hill, RN*

SAMPLE DOCUMENTATION

8/1/25, 1100, nursing

Nursing consultation with 13-year-old patient regarding anxiety about cause and source of nocturnal emissions. Patient also expressed concern about sexual myths he has heard from friends. Stated that much peer pressure exists to become sexually active. Patient admits to possessing little knowledge regarding sexual issues. Feels he cannot discuss sexuality with parents (who consented to this conversation) because it is not a topic that has been brought up in the past at home. Will conduct initial teaching session with patient to provide information and decrease anxiety about

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

priority concerns. Patient is willing to return to clinic for at least three more teaching sessions to expand knowledge base of sexuality.

N. Hill, RN

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

. Review the Nursing Care Plan 46-1 on pages 1896–1899 to help you hone your clinical reasoning and clinical judgment skills.

. Role-play with another student and perform the interview you would use to obtain a sexual history from the following people. Think about how you modified the interview in each situation and why. Identify what made you feel uncomfortable as either the nurse or the patient. Discuss how you can best address this discomfort.

- A mother voices concern that her 9-year-old son is frequently playing with his penis.
- An adult man appears distressed when they note that they have suddenly become impotent with their partner of many years.
- A high school girl says that her mother tells her something is wrong with her because she is attracted only to women.
- A new resident in a long-term care facility complains that he misses his privacy and has nowhere to make love.

. Describe how you would respond to a newly diagnosed woman with HIV who has had multiple partners and tells you that it is none of your business how she acquired the virus or what she plans to do now that she has it. Think carefully about what is at stake in terms of your response.

. You know a woman is uncomfortable about undergoing a pelvic examination, and you ask the male provider to wait for you before he begins the examination. He tells you he can't wait and doesn't need your assistance. You know the patient wants another woman in the room. How would you respond, and what is at stake? Does it matter if the reason for the patient's request to have you present is simply preference, is linked to a history of abuse, or is related to her cultural or religious beliefs?

PRACTICING FOR NCLEX

. A nurse is teaching parents about expected developmental aspects of sexuality in children. Which statements from parents indicate further teaching is needed? Select all that apply.

a. "When my 2-year-old son touches his genitals, I push his hand away and tell him 'No'."
b. "I should wean my infant by 4 months and encourage him to use a sippy cup."
c. "I should explain sexuality to my 9-year-old in a factual manner when they ask questions about their body."
d. "I should explain about body changes to my 11-year-old prior to them happening to alleviate their fears."
e. "I should teach my 10-year-old about contraception and ways to avoid sexually transmitted diseases."
f. "I should allow my teenager to establish their own beliefs and moral value system rather than sharing my own beliefs."

. A nurse is counseling an older couple regarding sexuality. Which statement from the couple should the nurse address?

a. "We're at the age when we should consider stopping sexual activity."
b. "We need more time for sexual stimulation than we used to."
c. "If we are unable to have sex, we can still have an intimate relationship."
d. "If we change our position, we can still have sex and be more comfortable."

. A nurse in a urology practice performs sexual health assessments of male older adults. Which patients would the nurse identify as having an increased risk for erectile dysfunction? Select all that apply.

a. Patient with a history of diabetes
b. Patient with a new partner
c. Patient with Parkinson disease
d. Patient with alcoholism
e. Patient taking antihypertensive medication
f. Patient who is a tobacco smoker

. A school nurse is providing sex education classes for adolescents. Which statement would the nurse include when describing normal sexual functioning?

a. "People are born with a certain amount of sexual drive, which can be depleted in later years."
b. "If you want to be a great athlete, sexual abstinence is necessary during training."
c. "A nocturnal emission (wet dream), is an indicator of a sexual disorder."
d. "It is natural for women to have as strong a desire for sex and enjoy it as much as men."

. During a checkup in a pediatric office, the mother of a school-aged boy tells the nurse that she is worried because she

has occasionally found him masturbating. She asks the nurse how she should handle this "problem." How would the nurse best respond to this mother's concern?

a. "Children should be taught not to masturbate because most people believe self-stimulation is wrong."
b. "Masturbation is a means of learning what a person prefers sexually; overreacting can lead the child to believe sex is bad or dirty."
c. "There are serious health risks associated with frequent masturbation, and the practice should be discouraged in children."
d. "Children who masturbate demonstrate sexual dysfunction and should be seen by a child psychologist."

. A patient who developed a pulmonary embolism (blood clot in the lung) after using oral contraceptives asks the nurse what she should do if she can no longer use "the pill." The nurse suggests which mechanical barrier for birth control?

a. Diaphragm
b. Transdermal contraceptive patch
c. Depo-Provera
d. Evra patch

. A 17-year-old college student calls the emergency department (ED) and tells the nurse they were raped by a professor. They want to come to the ED, but only if the nurse promises their parents will not be contacted. What should be the nurse's first priority?

a. Getting the patient into a safe environment and mobilizing support for them
b. Encouraging the student to disclose the name of the professor
c. Ensuring the student is assessed for pregnancy, STIs, and other complications
d. Convincing the student to tell their parents to receive their support

. A nurse is teaching patients about contraception methods. Which statement by a patient indicates a need for further teaching?

a. "Depo-Provera is not effective against sexually transmitted infections, but contraceptive protection is immediate if I get the injection on the first day of my period."
b. "The hormonal contraceptive, NuvaRing, protects against pregnancy by suppressing ovulation, thickening cervical mucus, and preventing implantation of the fertilized eggs."
c. "Abstinence is an effective method of contraception and may be used as a periodic or continuous strategy to prevent pregnancy and STIs."
d. "Withdrawal is an effective method of birth control that reduces risk for STIs."

. A nurse in a gynecology practice is assessing a patient reporting vaginal discharge that "smells bad and is green and foamy." She also reports burning upon urination and dyspareunia. The nurse suggests the patient and partner will need treatment for which STI?

a. Human papillomavirus (HPV)
b. Syphilis
c. Trichomoniasis
d. Herpes simplex virus

. A school nurse is providing information for parents of teenagers regarding the human papillomavirus (HPV) and the recommended HPV vaccination. What teaching point would the nurse include?

a. "HPV causes genital warts and cervical and other cancers."
b. "HPV causes a single painless genital lesion and can lead to sterility."
c. "Fifty percent of females between ages 14 and 19 years are infected with HPV."
d. "The HPV vaccination is only recommended for the female population."

. Students enrolled in a sexuality course are discussing people who achieve sexual arousal by looking at the body of someone other than a sexual partner. How would the students correctly name this behavior?

a. Masochism
b. Pedophilia
c. Voyeurism
d. Sadism

. An 18-year-old presents at a women's health care clinic seeking oral contraceptives before having heterosexual intercourse for the first time. She tells the nurse she doesn't know what to expect. What accurate statements by the nurse would be helpful? Select all that apply.

a. "During the excitement phase, your breasts swell and the nipples invert."
b. "Lubrication of the vagina seeps outside of the body making stimulation more pleasurable by decreasing friction."

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

c. "Your clitoris enlarges and emerges slightly from the clitoral hood."
d. "The first obvious sign of arousal in your partner is an erection of the penis caused by increased blood flow."
e. "The man's scrotum noticeably elevates, thickens, and enlarges."
f. "The skin of the penis and scrotum become pale in color."

. A nurse working in a gynecology practice screens patients for menstrual irregularities. Which patients would a nurse identify are at risk for menstrual cycle irregularities? Select all that apply.
a. Breastfeeding mother
b. Adolescent with anorexia
c. Individual abstaining from sexual intercourse
d. Patient diagnosed with pelvic inflammatory disease
e. Patient obsessed with exercising
f. Patient with a spinal cord injury

. A nurse in a gynecology clinic is obtaining a health history on a patient reporting pain during sexual activity. Which assessment question would be most appropriate for a patient who is experiencing dyspareunia?
a. "Do you currently have a new partner?"
b. "Have you been diagnosed with a neurologic disorder?"
c. "Do you take antihypertensive medication?"
d. "Do you regularly use antihistamines?"

. A nurse is providing health care for patients in a clinic located in a predominately LGBTQIA+ community. Which health disparities should the nurse keep in mind when planning care for this population? Select all that apply.
a. LGBTQIA+ youth are more likely to attempt suicide.
b. LGBTQIA+ youth are more likely to be homeless.
c. Lesbians are less likely to get preventive services for cancer.
d. Lesbians and bisexual females are more likely to be underweight.
e. Transgender people have a high prevalence of HIV and sexually transmitted infections.
f. LGBTQIA+ populations have low rates of tobacco, alcohol, and other drug use.

. Nurses in the emergency department (ED) have received education on identification of victims of human trafficking. Which patients would the ED nurse identify may be at risk? Select all that apply.
a. Those who work in hotels, nail salons, or home-cleaning services
b. Those who perform agricultural or ranch work
c. Those who show evidence of being controlled physically or psychologically
d. Those accompanied by someone who encourages them to share their own information
e. Those who produce identification documents (ID or passport)
f. Those who show the loss of the sense of time or space or not do know what city or state they are in

. A parent brings their preteen daughter to the pediatric office for an annual checkup. The parent asks when they should tell the child about menses. What information will the nurse provide?
a. "You can discuss this when you are ready."
b. "It isn't necessary to discuss menstruation until age 13."
c. "Most preteens have heard about menses from their friends. There is no rush."
d. "Menses begins between ages 10 and 13 years, so now is a good time."

ANSWERS WITH RATIONALES

. **a, b, c, e, f.** Self-manipulation of genitals is a normal behavior; parents should avoid telling a child this as "bad." Parents should avoid early weaning of infants to prevent oral deprivation. Parents should explain contraception and STIs to their adolescent children; it would be premature to do so for a 10-year-old. Parents should share their beliefs and moral system with their children. Parents should also give their children the desired information about sexuality in a clear, factual form and give them information about body changes before they experience them, to alleviate fears.

. **a.** Sexual activity need not be hindered by age, and couples who have been consistently sexually active throughout their lives may continue their intimate relationship for as long as they desire. Nurses should teach couples that adaptation to bodily changes is possible with use of comfortable positions for intercourse and increased time for stimulation as well as teach alternatives to coitus, such as caressing, hugging, and stroking, when coitus is impossible because of illness or disability.

. **a, d, e.** Risk factors for erectile dysfunction include history of diabetes, spinal cord trauma, cardiovascular disease, surgical procedure, alcoholism, and use of antihypertensives, antidepressants, or illicit drugs. Having a new partner

may be a risk factor for premature ejaculation, and a history of Parkinson disease may predispose the patient to delayed ejaculation. Smoking is not a risk factor for impotence.

. **d.** Physiologic studies indicate that, in some respects, the female's sex drive is not only as strong but may be even stronger than that of the male. The more consistently sexually active a person is, the longer the activity continues into the later years of life. Physiologically, the achievement of orgasm is rarely more demanding than most activities encountered in daily life; there is no scientific evidence that sex "weakens" a person. Erotic dreams that culminate in orgasms are normal common physiologic phenomena in at least 85% of men.

. **b.** Masturbation is a technique of sexual expression in which a person practices self-stimulation. It is a way for people to learn what they prefer during stimulation and what feels good. People masturbate regardless of sex, age, or marital status. Negative reaction or overreaction by parents to a child's masturbating can lead to a belief that the genitals and sex are bad or dirty, causing guilt or a feeling they are wrong. People may not masturbate due to guilt about it or believe self-stimulation is wrong. It is important to let patients know masturbation is not "dirty" and will not lead to blindness or insanity.

. **a.** The diaphragm is the only barrier method of contraception listed; all the other methods are hormonal.

. **a.** While the remaining options may be indicated, the priority is to ensure the safety of the woman and to get her the support she needs at this moment.

. **d.** Withdrawal offers no protection against sexually transmitted infections. An injection of depot medroxyprogesterone acetate (DMPA) can prevent pregnancy for 12 weeks, is 99.7% effective, and provides contraception immediately if administered on the first day of the female's period. The NuvaRing works by inhibiting ovulation in much the same way as oral contraceptives. Used appropriately, the vaginal ring is 99.3% effective in protecting against pregnancy. Abstinence is the most effective form of birth control, preventing pregnancy and STIs 100% of the time when practiced consistently and appropriately.

. **c.** Trichomoniasis causes a foul-smelling vaginal discharge that is thin, foamy, and green in color; it also causes itching of the vulva and vagina, burning on urination, and dyspareunia. HPV causes a profuse watery vaginal discharge, dyspareunia, intense pruritus, and vulvar irritation. Syphilis causes a single painless genital lesion 10 days to 3 months after exposure and generalized skin rash, enlarged lymph nodes, and fever that may appear 2 to 4 weeks after appearance of primary lesion and may last for several years. Herpes presents as single or multiple painful vesicles that rupture and form ulcer-like lesions, which form scabs as they heal.

. **a.** HPV causes genital warts and cervical and other cancers. It manifests as pale, soft, papillary lesions found around the internal and external genitalia, perianal and rectal areas of the body. One in four young females between ages 14 and 19 years is infected with at least one of the most common STIs, which include the human papillomavirus (HPV). The HPV vaccination is recommended for males and females.

. **c.** Voyeurism is the achievement of sexual arousal by looking at the body of someone other than a person's own sexual partner. Masochism refers to gaining sexual pleasure from the humiliation of being abused. Pedophilia is a term used to describe the practice of adults gaining sexual fulfillment by performing sexual acts with children. Sadism refers to the practice of gaining sexual pleasure while inflicting abuse on another person.

. **b**, **c, d, e.** It is appropriate to provide education about sexuality and sexual responses. The nurse could teach that during the excitement phase, the female breasts swell and the nipples become erect and hard to the touch. Lubrication of the vagina seeps along the vulvar creases decreasing friction and making stimulation of the genitals more pleasurable. The upper two thirds of the vagina enlarge and expand. The clitoris enlarges and emerges slightly from the clitoral hood. The labia also enlarge and separate and turn a deep rosy-red with arousal. The first obvious sign of arousal in the male is an erection of the penis caused by increased pelvic congestion of blood. The scrotum noticeably elevates, thickens, and enlarges. The skin of the penis and scrotum turns a deep reddish purple in response to congestion and arousal. Male nipples may also harden and become erect. The nurse should also discuss contraception, preventing STIs, and the patient's right to say no if she chooses.

. **a, b, d, e.** Causes of menstrual cycle irregularities include pregnancy or breastfeeding, eating disorders, extreme weight loss, excessive exercising, and pelvic inflammatory disease, as well as many other causes. Abstaining from sex and spinal cord injuries are not causes of menstrual irregularities.

. **d.** Factors contributing to dyspareunia include diabetes; hormonal imbalances; vaginal, cervical, or rectal disorders; antihistamine, alcohol, tranquilizer, or illicit drug use; and cosmetic or chemical irritants to genitals.

. **a**, **b, c, e.** LGBTQIA+ youth are two to three times more likely to attempt suicide and be homeless. Lesbians are less likely to get preventive services for cancer. Transgender people have a high prevalence of HIV and sexually transmitted infections. LGBTQIA+ youth are two to three times more likely to attempt suicide. Lesbians and bisexual females are more likely to be overweight or obese. LGBTQIA+ populations have the highest rates of tobacco, alcohol, and other drug use in the country. These health issues are partly thought to be the effects of chronic stress resulting from stigmatization.

. **a, b, c, e, f.** Victims of human trafficking can be any age. The nurse observes for those engaging in sex work, agricultural, or ranch work; working in hotels, massage parlors, nail salons, or home-cleaning services; performing

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

domestic labor (cleaning, childcare, eldercare, etc.); working in restaurants, bars, or cantinas; and begging, street peddling, or door-to-door sales. Victims of human trafficking may exhibit evidence of being controlled either physically or psychologically, an inability to leave home or their place of work, or an inability to speak for themselves or share their own information. Information is provided by someone accompanying the individual, and they do not have control of their own identification documents (ID or passport). They have few or no personal possessions, may owe a large debt that they are unable to pay off, and may demonstrate loss of sense of time or whereabouts.

. **d.** Puberty begins for most girls with development of secondary sex characteristics, and menarche begins at about age 12 years but may occur anywhere between ages 8 and 17 years. Information regarding body changes is needed to alleviate fears and should be given to the child before puberty begins. The focus should be on the daughter's needs, not the parent's need.

Spirituality

Kevin Gargan

Kevin, a 38-year-old divorced man on a step-down unit after treatment for a myocardial infarction, asks the night nurse, “Did you ever give much thought to whether or not there is a God?” Kevin listed his religion as Protestant but says it’s been a long time since he went to church or prayed.

Choi Min Lai

Choi, a member of the Hmong culture from Laos, is refusing to allow health care providers to perform a series of surgical repairs to correct severe deformities of his 8-year-old son’s feet. “In our culture, the deformity is a sign of spiritual favor and good luck. Because of Kou’s condition, a warrior ancestor whose feet were wounded in battle will no longer be spiritually trapped. You see, Kou is special.”

Margot Zeuner

Margot, a 75-year-old woman, is taking care of her 80-year-old husband with advanced Alzheimer’s disease, who was just discharged from the hospital and requires constant supervision. When visited at

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

home, she says, “I really miss going to church and seeing everyone. They’re so supportive. That was the one thing that helped to keep me going.”

Learning Outcomes

After completing the chapter, you will be able to accomplish the following:

. Identify the three spiritual needs believed to be common to all people.
. Describe the influences of spirituality on everyday living, health, and illness.
. Differentiate life-affirming influences of religious beliefs from life-denying influences.
. Distinguish spiritual beliefs and practices of major religions practiced in the United States.
. Identify five factors that influence spirituality.
. Perform a nursing assessment of spiritual health, using appropriate interview questions and observation skills.
. Develop problem identifications that correctly identify spiritual problems.
. Describe nursing strategies to promote spiritual health, and state their rationale.
. Plan, implement, and evaluate nursing care related to select problem identifications involving spiritual problems.

suffering spiritual health

Paying attention to the spiritual dimension of health and well-being is integral to holistic person-centered care. Patients facing the losses and limits related to injury, disease, or aging begin to evaluate what is important in life, and often ask the “big questions”: Is there a God or transcendent being? Does life have meaning and purpose? Am I dying? Is there anyone I can trust to be with me during this hard time? Nurses skilled in spiritual care are able to identify and elicit the inner resources of patients and family caregivers to promote health and healing with sensitivity to such questions. Many nurses who describe themselves as professional healers use the terms “vocation” or “calling” to describe the work of nursing. They claim to be “standing on holy ground” when they create that hospitable place where patients can expose their vulnerabilities and face their biggest concerns. We learn, with great humility, that sometimes the most important things we do are accomplished simply by being present to those we serve (see Through the Eyes of a Caregiver on pages 1908–1909). A Baptist woman with a life-threatening cancer who had shared the importance of her spirituality with me recently wrote to me:

> When you made a cross on my forehead with your thumb, it felt unfamiliar—but perfect. Like a blessing with no conditions—no strings. How liberating. Affirming. Loving. And to think you did it with just your thumb. And your heart. Thank you.

SPIRITUAL DIMENSION

The human "spirit" dimension was first recognized in ancient cultures. One person often played the roles of both priest and health care provider, ministering to the spirit and the body. Over the years, however, medicine and religion evolved separately. Not until the holistic health movement took root was the person once again viewed as an integrated whole of body, mind, and spirit. Health care practitioners began again to probe the relationships among physical, psychological, social, and spiritual health. Two models are currently used to illustrate these relationships (Fig. 47-1 on page 1908). In the integrated approach, the physio-psycho-socio-spiritual model has four equal dimensions, each of which influences the other. In the unifying approach, the spiritual dimension grounds the physiologic, psychological, and sociologic dimensions. While it is interesting to interview professional healers about which model is more consistent with their experience, both demand from the nurse greater competence in identifying and meeting spiritual needs than most practicing nurses today display. National guidelines now mandate spiritual care—see the Joint Commission requirements and the National Consensus Project for Palliative Care (2018). In 2016, the Health Care Chaplaincy Network developed the most comprehensive evidence-based indicators that demonstrate the quality of spiritual care in health care in a move aimed at advancing spiritual support and meeting the needs of patients, their families, and health care institutions.

According to Shelly and Fish (1988), three **spiritual needs** underlie all religious traditions and are common to all people regardless of whether or not they belong to a particular religious tradition:

. Need for meaning and purpose
. Need for love and relatedness
. Need for forgiveness

Although nurses may differ in their beliefs about how involved they should become in meeting patients' spiritual needs, it is impossible to nurse patients well while ignoring the spiritual dimensions of health. Nurses can assist patients to meet spiritual needs by offering a compassionate presence; assisting in the struggle to find meaning and purpose in the face of suffering, illness, and death; fostering relationships (with a higher being or other people) that nurture the spirit; and facilitating the patient's expression of religious or spiritual beliefs and practices (e.g., see the Reflective Practice box).

CONCEPTS RELATED TO SPIRITUALITY AND SPIRITUAL HEALTH

Spirituality, faith, religion, and the influence of these elements on everyday living and health and illness are important concepts to understand when caring for patients. Although some use the words *spirituality, faith,* and *religion* interchangeably, there are distinctions. These and other concepts are explored in the following sections.

QSEN Reflective Practice: Cultivating QSEN Competencies

CHALLENGE TO INTELLECTUAL SKILLS

During my pediatric rotation, I encountered a Hmong family from Laos whose 8-year-old son, Kou, had severe deformations in his feet. It seemed as if the entire health care team was united to persuade, cajole, and if necessary, force Choi Min Lai, Kou's father, and his mother to authorize a series of surgical repairs. But the parents were adamant in their refusal. In their culture, the deformity was a sign of spiritual favor and good luck. They believed that a warrior ancestor whose own feet were wounded in battle would be released from a form of spiritual entrapment because of their son's condition. This made Kou special in their community. I admired their fierce championing of their beliefs, but my heart ached for Kou because of the difficulties he would face in the U.S. society if his feet were not repaired. I didn't know anything about the Hmong culture or their beliefs. As a result, I didn't know which side I should support. I also didn't know much about the legal rights of the parents to refuse a procedure that, although not lifesaving, would clearly benefit their son.

Thinking Outside the Box: Possible Courses of Action

- Remain detached from the conflict and just observe.
- Try to learn more about the family's cultural and religious beliefs to see if this information could be helpful.
- Contact the hospital attorney to find out about the legal rights of the parents to refuse a procedure that, while not lifesaving, would clearly benefit their son.
- Use my relationship with the family to try to persuade them to comply.
- Use my knowledge of Kou and his family to try to persuade the health care team to respect their wishes.

Evaluating a Good Outcome: How Do I Define Success?

- The health care team chooses a course of action that is beneficial to Kou and simultaneously respects the

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

family's religious and cultural beliefs.
- We respect the legal rights of this family.
- My knowledge of the Hmong religion and culture is increased.
- I am faithful to my advocacy obligations.

Personal Learning: Here's to the Future!

Unfortunately, this issue was not resolved during my rotation. In fact, the conflict continued to grow. When I completed my rotation, the hospital was appealing to the court to force the parents to accept surgery. I came to believe that the rights of the parents should be respected. Their cultural community was so strong, and they clearly did not see Kou's condition as a correctable "health problem" but rather a blessing to be enjoyed. While a few other nurses felt the way I did, the health care providers and the social worker felt strongly that the parents were wrong. I learned much about the Hmong culture, realizing that my practice will continue to surprise me as I encounter patients and families with beliefs and practices very different from mine. As a result of this experience, I hope I will keep an open mind and always be ready to learn.

QSEN SELF-REFLECTION ON QUALITY AND SAFETY COMPETENCIES DEVELOPING KNOWLEDGE, SKILLS, AND ATTITUDES FOR CONTINUOUS IMPROVEMENT

Do you agree with the criteria that the nursing student used to evaluate a successful outcome? Why or why not? What *knowledge, skills,* and *attitudes* do you need to develop to continuously improve the quality and safety of care for patients like Kou and his family?

Patient-Centered Care: How would you develop a respectful and successful partnership with Kou and his family, given that their culture is so different? How can you best communicate empathy and respect given the conflict created by their wishes?

Teamwork and Collaboration/Quality Improvement: What communication and interpersonal skills do you need to improve to ensure that you function as a member of the patient-care team when members of the team are so divided? The social worker? Other members of the health care team? What other team members can be called upon to provide needed assistance in clarifying this family's legal rights? What does quality care for Kou and his family "look like"?

Safety/Evidence-Based Practice: What does the evidence point to as "best practice" for Kou? What safety needs does he have and how can you meet them?

Informatics: Can you identify the essential information that must be available in Kou's electronic record to support safe patient care and coordination of care? Are there smart devices or online resources you can use to learn more about the Hmong culture? Can you think of other ways to respond to or approach the situation? What else might the nursing student have done to ensure a successful outcome?

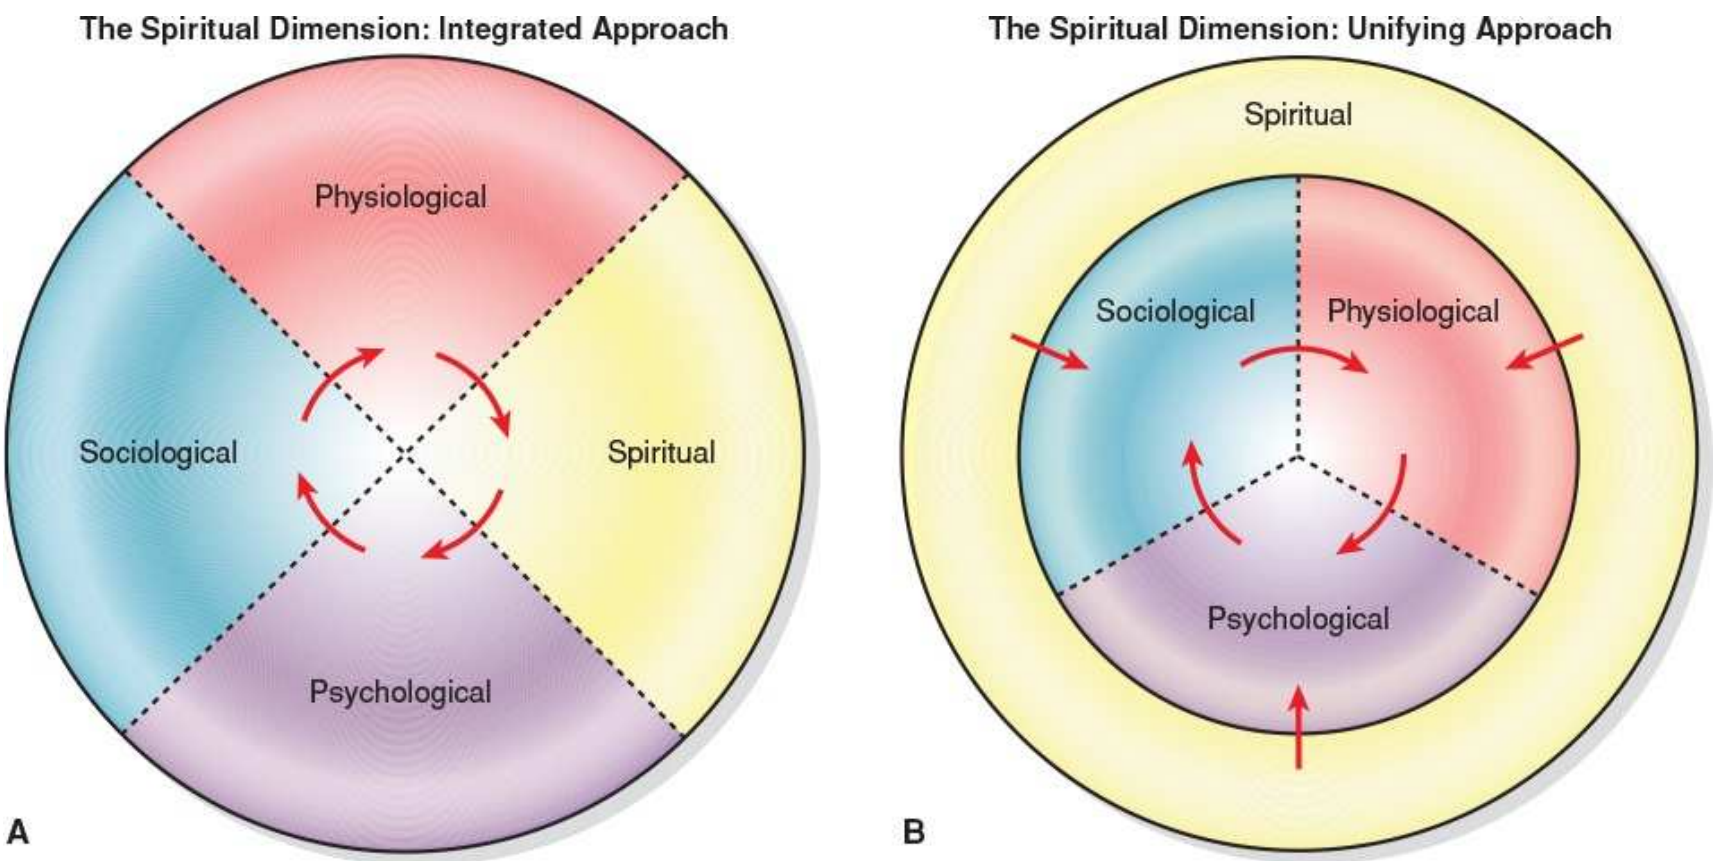

FIGURE 47-1. Spiritual dimensions. No consensus exists about the role of the spiritual dimension in health. **A.** The integrated approach views each of the four dimensions as equal and influencing one another. **B.** The unifying model grounds the physiologic,

psychological, and social dimensions in the spiritual dimension. (*Source:* Redrawn by permission from Springer Nature from Farran, C. J., Fitchett, G., Quiring-Emblen, J. D., & Burk, J. R. [1989]. Development of a model for spiritual assessment and intervention. *Journal of Religion and Health*, *28*[3], 185–194.)

Through the Eyes of a Caregiver

My name is Janine Landry and I love nursing! I especially have a passion for emergency department (ED) nursing, and I'm pleased to be employed in a faith-based community hospital. I don't feel like I have a job, but rather I look at it as an amazing opportunity to meet people from diverse cultures and beliefs. My work has enabled me to learn and grow both professionally and personally. My dream has always been to become a nurse, to have the opportunity to follow my heart and the purpose of my life—that is, to "*make a difference*." I strive to create an environment of hope and healing and to have an impact on the people from the vulnerable population we serve. I would like to recount a true story that encompasses all that I believe in, and live, as a registered nurse.

I'll never forget the day I walked into the Grey Nuns Hospital and noticed the mission statement posted on the wall. It began with "Healing the Body, Enriching the Mind, Nurturing the Soul," and went on to express the hospital's values and beliefs, all of which I truly support. This mission statement helps to guide my decisions and actions I make every day, and in all areas in which I work. As a clinical nurse educator, I have made it my habit to instruct our newly hired staff to locate the mission statement; read, understand, and respect it; and most importantly, to live it!

In the ED, we often have repeat visitors and one particular gentleman comes to mind. Fred (not his real name) was a "high-maintenance" kind of guy who always appeared cranky. He had silky white hair, bright blue eyes, wore a constant frown on his face, and often demanded a lot of attention. Fred had a chronic condition, which resulted in him visiting us on a regular basis. At that time, I was working on the floor, and I was often assigned to be his nurse. Fred was somewhat gruff when he spoke to people, and he never called me by my given name, Janine. Although I would remind him, he still chose to call me a myriad of other names.

One day while Fred was in the department awaiting admission to the medical unit, I served him his breakfast tray. He snarled and refused to eat it. I looked at him and said "Fred, you're not eating." He grumbled under his breath and said, "No, I don't want to eat this." "Fred, may I remind you that you're at the Grey Nuns Hospital, and did you know that every meal prepared here is made with love … and this breakfast was made especially for you?" "Really … it was made with love?" "Absolutely!" Not surprisingly, Fred ate all his breakfast, and later on, he ate his entire lunch. When his wife and friends came to visit him, he would tell them how amazed he was to find out that all his meals were made with love. Every time his wife and daughter would come and visit him, I would look at them and wink; this always made them smile and giggle.

A few months later, Fred was a patient once again. Guess which nurse was assigned to him? You're right … it was me again. While I was busy changing a wound dressing on his leg, a message came over the hospital intercom system. Fred asked, "What's that noise I hear every morning in this hospital?" "Fred, what may be noise to your ears, is known as a prayer or a reflection to others." He asked, "What do you call it?" "I personally call it Hope!" "Hope?" "Yes, let me explain. Do you like Neapolitan ice cream?" "Yeah!" "What's your favorite flavor?" "I like all the flavors, but I especially enjoy chocolate and my wife and daughter like the vanilla and strawberry flavors. Why do you ask?" "Imagine this; we'll compare Hope to an entire brick of Neapolitan ice cream that has three individual flavors, right?" Fred nodded and agreed. "For some people, in order to have hope, they need to taste that vanilla flavor, which represents *faith,* and depending on what their beliefs are or what they're faced with at that particular moment, having faith may require *courage;* that would be the strawberry flavor. Most importantly, to have hope, you need *love*—a sense of love for yourself, to be able to receive love and to love others unconditionally, and for some people it also means loving God. So, just think how lucky you are Fred, knowing your favorite flavor is chocolate … that's awesome because everyone knows that chocolate and love are both really good for your heart! You can enjoy each flavor individually … and that's o.k.… or you can swirl the ice cream and mix it all together to make one flavor; a delicious flavor called HOPE!"

Fred really didn't know how to respond. He looked up at me with his big bright blue eyes and a puzzled look on his face. He then asked me "Are you a tree hugger?" I said no! "Would you ever hug a tree?" I thought about it, and I said, "You know, for the right reason and at the right time, yes, I guess I would hug a tree, because a tree symbolizes creation, growth, and change." Fred looked up at me and said, "If I was a tree, what type of a tree would I be?" I quickly replied "Oh … without a doubt … you would be an ol' crabapple tree!" Fred started to laugh, it was the first time I had ever heard him laugh, and this laughter came from his toes.

A few weeks later, as I was walking in the main lobby of the hospital, I heard a familiar gruff voice calling out to me. I turned around, and sure enough it was Fred and his wife. He asked me to close my eyes and to put out my hand. When I opened up my eyes, Fred had placed the shiniest, most perfect red apple in my hand. I was speechless but realized that we really had no need for words: our eyes spoke volumes. I'll never forget that moment.

A few months later, when Fred returned to the ED, I learned that his wife had recently passed away. Fred was depressed and acutely ill; his chronic condition had worsened, and the cardiologist informed me that Fred was dying and that he was made aware of this. I quickly notified his daughter and then went to his bedside to support him, but he shouted, "get out, get away from me, and leave me alone!" I respected his wishes by leaving the room; but I

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

intentionally left the curtain slightly open so that I could continue to monitor him from the nursing desk. While I was charting, I sensed that he was watching me, so I looked up and just like the time before, our eyes silently spoke to each other.

Fred was deteriorating quickly, and his daughter hadn't arrived yet. My shift was over but I couldn't imagine leaving him alone, so I went into his room to say goodnight. Although we both knew it wasn't really "goodnight," I asked him if I could come and sit next to him, and he simply raised his finger and nodded his head. I sat next to him, and for the longest time neither one of us said anything. I held his hand and looked into his blue eyes and said, "what do you need?" His response was "this ol' tree needs a hug!" So, I held him tightly in my arms for the longest time, and when his daughter arrived, I gently laid him back and said "good bye." Next, when I stood up, the most amazing thing happened: Fred looked up at me, and despite his labored breathing, he whispered, "Thank you … thank you, Janine." This was truly a precious moment for me because it was the first and only time Fred called me by my given name.

Shortly thereafter, he died. I will never forget this experience because when I walked away, I was thinking about the time we had spent together, and although there were many challenging times with this gentleman, I realized that I had grown to respect him. He died with dignity, because I knew who he was, I took the time to get to know what was truly at the "core" of this man. In essence, I got to know what was in his heart … and he was truly a gift to me!

—Janine Landry

Spirituality

Spirituality is anything that pertains to a person's relationship with a nonmaterial life force or higher power. While one person describes spirituality in terms of coming to know, love, and serve God, another speaks of transcending the limits of body and experiencing a universal energy.

Aspects of spirituality include the following:

- Spirituality is experienced as a unifying force, life principle, essence of being.
- Spirituality is expressed and experienced in and through connectedness with nature, the earth, the environment, and the cosmos.
- People express and experience spirituality in and through connectedness with other people.
- Spirituality shapes self-becoming and is reflected in a person's being, knowing, and doing.
- Spirituality permeates life, providing purpose, meaning, strength, and guidance, and shaping the journey.

While analyzing concepts of spirituality through a review of related literature, nurse scholar Bernice Golberg (1998) identified the following phenomena: meaning, **presencing** (standing in the presence of another consciously believing in —and affirming—their capacity for wholeness), empathy/compassion, giving hope, love, religion/transcendence, and touch and healing. All appeared to be products of relationships, some physical (presencing, touch, and healing), and others emotional (meaning, empathy/compassion, hope, love, and religion/transcendence). Golberg combined these and gave spirituality the label "connection" (1998, p. 836). In 2021, the American Nurses Association highlighted the importance of compassionate presence by including it in their definition of nursing. "Nursing integrates the art and science of caring and focuses on the protection, promotion, and optimization of health and human functioning; prevention of illness and injury; facilitations of healing; and alleviation of suffering through compassionate presence" (p. 1).

> In the words of theologian Karl Rahner, spirituality is … simply the ultimate depth of everything spiritual creatures do when they realize themselves—when they laugh or cry, accept responsibility, love, live and die, stand up for truth, break out of preoccupation with themselves to help the neighbor, hope against hope, cheerfully refuse to be embittered by the stupidity of daily life, keep silent, not so that evil festers in their hearts, but so that it dies there—when, in a word, they live as they would like to live in opposition to selfishness and to the despair that always assails us (1971, p. 229).

Faith

Faith generally refers to a confident belief in something for which there is no proof or material evidence. It can involve a person, idea, or thing, and is usually followed by action related to the ideals or values of that belief. For example, if I have faith in my doctor, parish nurse, or healer, I am more likely to adhere to a prescribed regimen or plan of care and to experience benefits. Similarly, patients who believe in a loving and all-powerful being who knows them and cares for them are often better able to cope with the suffering related to injury and illness. The declaration made by the World Conference of the Religions for Peace in Kyoto, Japan, in 1970 is an excellent example of a confident belief in something for which there is no proof or material evidence. At this conference, Baha'i, Buddhist, Confucianism, Christian, Hindu, Jain, Judaism, Muslim, Shintoist, Sikh, and others discovered that the beliefs that unite them were more important than those that divided them. They discovered that they shared:

- A conviction of the fundamental unity of the human family, of the quality and dignity of all human beings

- A sense of the sacredness of the individual person and the person's conscience
- A sense of the value of the human community
- A belief that love, compassion, unselfishness, and the force of inner truthfulness and of the spirit have ultimately greater power than hate, enmity, and self-interest
- A sense of obligation to stand on the side of the poor and the oppressed and against the rich and the oppressors
- A profound hope that good will finally prevail

Faith is a term also used to describe a cultural or institutional religion, such as Judaism, Islam, or Confucianism. An **atheist** is a person who denies the existence of a higher power; an **agnostic** is one who holds that nothing can be known about the existence of a higher power. Atheists and agnostics deserve respect for what they choose to believe, just as do those who accept a particular religious creed.

Religion

Religion can be defined as an organized system of beliefs about a higher power that often includes set forms of worship, spiritual practices, and codes of conduct. Although it is impossible for nurses to be knowledgeable about all religions, we are better able to meet patients' spiritual needs when we understand their religious beliefs and practices. These can directly influence patients' responses to illness and suffering, self-care practices such as diet and hygiene, birth and death rituals, biologic sex roles, spiritual practices, and moral codes. The beliefs and health practices of major religious traditions in the United States are briefly described in Table 47-1. Please remember that these are generalizations and that not all members of religious traditions hold the same beliefs or practices. Also understand that this is not a comprehensive list, especially as the U.S. population becomes increasingly diverse.

The U.S. Religious Landscape Survey of 35,000 Americans by the Pew Research Center's Forum on Religion & Public Life (2015) found that most Americans were religious and most had a nondogmatic approach to faith. At the time of the survey, the largest percentage of Americans—70.6%—were Christian, and 5.9% belonged to non-Christian faiths (Jewish, Muslim, Buddhist, Hindu, and other world religions). Religious "nones" (those unaffiliated with a religion) represented 22.8% of Americans, and of these 3.1% were atheist and 4% were agnostic.

This study found a modest drop between 2007 and 2014 in the percentages of those who say they believe in God, pray daily, and regularly go to church or other religious services. This recent decrease in religious beliefs and behaviors is largely attributable to the "nones"—the growing underrepresented group of Americans, particularly in the Millennial generation, who say they do not belong to an organized religion. In addition:

- Most Americans who are affiliated with a religion do not believe their religion is the only way to salvation. Most also believe that there is more than one true way to interpret the teachings of their religion.
- More than half of Americans rank the importance of religion very highly in their lives, attend religious services regularly, and pray daily.
- A plurality of adults who are affiliated with a religion want their religion to preserve its traditional beliefs and practices rather than either adjust to new circumstances or adopt modern beliefs and practices.
- Significant minorities across nearly all religious traditions see a conflict between being a devout person and living in a modern society.
- The relationship between religion and politics is particularly strong with respect to political ideology and views on social issues such as abortion LGBTQIA, with the more religiously committed adherents across several religious traditions expressing more conservative political views.
- Americans are very similar in some basic religious beliefs. For instance, Americans are nearly unanimous in saying they believe in God (91%); large majorities believe in life after death (74%) and believe that Scripture is the word of God (63%).
- More than three quarters of American adults (78%) believe there are absolute standards of right and wrong, with a majority (52%) saying they rely primarily on practical experience and common sense for guidance regarding right and wrong. Far fewer say they rely mainly on their religious beliefs (29%), and fewer still say they rely on philosophy and reason (9%) or scientific information (5%).
- The United States has largely avoided the secularizing trends that have reshaped the religious scene in recent decades in European and other economically developed nations—but not entirely. The Landscape Survey documents, for example, that the number of Americans who are not affiliated with a religion has grown significantly in recent decades, with the number of people who today say they are unaffiliated with a religious tradition (16% of U.S. adults) more than double the number who say they were not affiliated with a religion as children (7%).

Table 47-1 Beliefs and Health Care Practices of Major Religious Traditions in the United States

RELIGION	BELIEFS	SELECT HEALTH CARE PRACTICES
Adventist	Believe in the person's choice and God's sovereignty. The body is believed to be the temple of the	• The taking of all narcotics and stimulants is prohibited because the

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

	Holy Spirit.	body is the temple of the Holy Spirit and should be protected. Many groups prohibit meat. • Many regard Saturday as the Sabbath. • Approach to health care is holistic.
American Muslim Mission	Accept the *Koran* as their sacred scripture (see Islam); most stress the importance of cooperation among Black individuals in business and education to build self-esteem.	• Members are encouraged to obtain health care provided by members of the Black community. • Major tenets involve prayer rituals, dietary restrictions (prohibitions against pork and alcohol), hygiene (extreme cleanliness), lifestyle modifications, and marital faithfulness.
Baha'i International Community	Believe in a basic harmony between religion and science	• Seek out competent medical care and pray for health. • Obligatory prayers, holy days, and the 19-day fast. • Permanent sterilization is prohibited, and abortion is discouraged.
Buddhism	Buddha—or "the Great Physician"—taught the Four Noble Truths to indicate the range of "suffering," its "origin," its "cessation," and the "way" that leads to its cessation. The real cause of human suffering is ignorant craving. The Noble Eightfold Path—which consists of right views, aspirations, speech, conduct, mode of livelihood, effort, mindfulness, and concentration—leads to the cessation of suffering.	• Buddhists do not outwardly proclaim healing through faith. However, spiritual peace and liberation from anxiety attained through the awakening to Buddha's wisdom may be an important factor in expediting healing and the recovery process. • Accepts modern science. The doctrine of avoidance of extremes is applied to the use of drugs, blood, vaccines. • Buddhism does not condone taking lives of any form. • Check with the patient about any special diet restrictions and the observance of holy days.
Christian Scientist	They deny the existence of health crises; sickness and sin are errors of the human mind and can be overcome by altering thoughts, not by using drugs or medicines.	• They will use orthopedic services to set a bone but decline drugs and, in general, other medical or surgical procedures. • They do not allow hypnotism or any form of psychotherapy, which alters the "Divine Mind." • A Christian Science Practitioner may be called to administer spiritual support. • Alcohol and tobacco are not used.
Church of Jesus Christ of Latter Day Saints (Mormons)	Devout adherents believe in divine healing through the "laying on of hands," though many do not prohibit medical therapy. The Church maintains an extensive and well-funded welfare system, including financial support for the	• Mormons who have served a full-time mission are more likely than those who have not served a mission to see believing Joseph Smith saw God, helping the poor and avoiding coffee

	sick.	and tea are essential for being a good Mormon. • Church leaders encourage Mormons to keep at least three months of food supplies on hand.
Confucianism	Inherent in Confucianism is the appreciation of life and the desire to keep the body from untimely or unnecessary death.	• Appreciate life and desire to keep the body from untimely or unnecessary death. • Historically emphasized public health solutions to impending health problems.
Daoism (Taoism)	Health is a manifestation of the harmony of the universe, obtained through the proper balancing of internal and external forces. Implicit throughout the Daoist tradition is the tendency to understand salvation in the biomedical sense of health and qualitative improvement and prolongation of human life. The universal principle of the Tao is the mysterious biologic and spiritual life rhythm or order of nature.	• There is a “medicinal” concern for maintaining and prolonging human health and life (sheng). Knowing and living a natural life—following the Tao—is the secret of both health and sagehood. • Long tradition of seeking pragmatic medical techniques, along with its religious techniques of meditation and ritual for establishing a harmony of body and spirit, humanity, and nature (holistic approach).
Hinduism	Doctrine of Transmigration. Moral factors, linked with the all-embracing doctrine of “karma,” are believed to be significant in promoting health or causing disease.	• Hindu medicine shows a surprising openness to new ideas, at least in respect to practical treatment. • Many Hindu dietary restrictions conform to individual sect doctrine. • The nurse administering medications should avoid touching the patient’s lips. • Certain prescribed rites are followed after death; disposal of the body is by cremation.
Islam	Allah, one God, who is only one, all seeing, all hearing, all speaking, all knowing, all willing, all powerful. Must be able to practice the Five Pillars of Islam. May have a fatalistic view of health.	• Obligatory prayers, holy days, fasting (Ramadan), and almsgiving. • Koranic law and customs that influence birth, diet (eating pork and drinking alcohol are forbidden), care of women, death and prayer rituals. • Some Muslim women are not allowed to make independent decisions; husbands may need to be present when consent is sought.
Jehovah’s Witnesses	They oppose the “false teachings” of other sects; opposition often extends to modern science, including medicine.	• Blood transfusions violate God’s laws and therefore are not allowed. • The courts have not supported the right of Jehovah’s Witness parents to refuse lifesaving treatment for their children. • Use of alcohol and tobacco are discouraged.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Judaism	Formation closely bound with a divine revelation and with commitment to obedience to God's will. The Hebrew Bible is the authority, guide, and inspiration of the many forms of religion of the Jewish people (currently Reform, Conservative, Orthodox).	• For observant Jewish: special needs in the areas of diet, birth rituals, male and female contact, and death. • Treatment and procedures should not be scheduled on the Sabbath.
Native American Religions	Difficult to generalize; notion of cosmic harmony, emphasis on directly experiencing powers and visions and a common view of the cycle of life and death. Death is not the end but the beginning of new life (reincarnation or transcendent hereafter).	• Rituals mark important life changes: birth, puberty, initiation rites, death. • Medicine men and women have specialized spirits from whom they receive the mission to cure. • Common therapeutic measures: sucking, blowing, and drawing out with a feather fan.
Protestantism	Worship of the one God revealed to the world through Jesus Christ. Love of neighbor is a central tenet. Other beliefs include sin, redemption, salvation, and a final accounting with God. Care of the sick is encouraged. God the author and giver of life is also the healer. Most accept modern medical science.	• Religious practices vary according to denomination; may include prayer, faith healing, "laying on of hands," and anointing. • Sacraments: baptism, communion, confirmation.
Roman Catholicism	Worship of the one God revealed to the world through Jesus Christ. Love of neighbor is a central tenet. Other beliefs include sin, redemption, salvation, and a final accounting with God. Care of the sick is encouraged. God the author and giver of life is also the healer. Human life is a gift of God. Many take an antiabortion stance; most accept modern medical science.	• Importance of private devotions and Mass attendance on Sunday. • Seven sacraments (importance of baptism, Eucharist, penance, and the anointing of the sick). • Dietary habits. • Sexual ethical norms. • Only natural means of birth control; abortion, euthanasia, and sterilization are forbidden.
Sikhism	Draws on features from Islam and Hinduism to establish a reformist movement with the aim of creating a new world order based on equality and social justice for all. The holy book is a code of conduct for daily life and an instruction for reaching true understanding and unity with God, the ultimate goal.	• Respect the special dress code including "Kesh," uncut hair for both men and women, and "Kara," a steel bangle worn on the right wrist. Removing a turban without permission, except in an emergency, is considered an insult. • Sexual activity is allowed only within marriage. Large families are encouraged, more for cultural than religious reasons. • Sikh individuals prefer a nurse or doctor of the same sex.
Unitarian Universal Association of Churches and	Encourage creativity, reason, and living an ethical life. No member is required to adhere to a given	• Free to accept what they take to be best for their health.

Fellowships	creed or set of religious beliefs. The inherent worth and dignity of every person is affirmed.

Disclaimer: Please note not all individuals within any tradition subscribe to the same beliefs.

This chapter is being written during the COVID-19 pandemic, during which in-person religious services were suspended for many different religious groups, and in-person wedding and funeral or memorial services were suspended. Many are wondering if the changes during the pandemic will affect the practice of religion once people can return safely to their places of worship.

Nurses who are unfamiliar with a patient's religion can gain valuable knowledge by discussions with the patient and the patient's family and spiritual advisor.

Recall **Choi Min Lai**, the father of the 8-year-old boy with foot deformities who is refusing surgical repair based on his cultural and religious beliefs. Researching information about the patient's beliefs would be essential in planning this family's care and advocating for the patient and his family.

Never presume to know what a patient's religious beliefs or practices are just because you have learned the patient's faith tradition. Many religious groups and people work out their own set of beliefs and practices, which may or may not be compatible with the tradition at large. Also, you should not interpret the fact that a patient does not belong to an organized religion to mean that the patient has no spiritual needs; a person may be deeply spiritual yet not profess to belong to an organized religion.

Hope

Closely related to spirituality, faith, and religion, **hope** is the ingredient in life responsible for a positive outlook, even in life's bleakest moments. It enables a person both to consider a future and to work to actively bring that future into being. Hope originates in imagination but must become a valued and realistic possibility in order to energize action. Hope allows a person to embrace the reality of suffering without escaping from it (false hope) or being suffocated by it (despair, helplessness, hopelessness). Hope is unique to each person. Box 44-6 on page 1813 contains a set of suggestions, developed by an interdisciplinary team, for enabling hope in the terminally ill that can apply to any situation in which people feel hopeless (Creen, 2002).

Love

Earlier, we noted that people express and experience spirituality in and through connectedness with other people. There is a basic human need to love and be loved, and we cannot be spiritually whole, spiritually healthy, unless this need is met. Mother Teresa wrote:

> "The greatest disease in the West today is not TB or leprosy; it is being unwanted, unloved, and uncared for. We can cure physical diseases with medicine, but the only cure for loneliness, despair and hopelessness is love. There are many in the world who are dying for a piece of bread but there are many more dying for a little love. The poverty in the West is a different kind of poverty—it is not only a poverty of loneliness but also of spirituality."

Suffering

Eric Cassell (1991), a physician who has written eloquently on human **suffering** describes suffering as a specific state of distress that occurs when the intactness or integrity of the person is threatened or disrupted. It lasts until the threat is gone or integrity is restored. Suffering involves some symptom or process that threatens the patient because of fear, the meaning of the symptom, and concerns about the future. The meanings and the fear are personal and individual, so that even if two patients have the same symptoms, their suffering would be different. While it has taken health care professionals decades to get serious about managing physical pain, too many of us remain unskilled in identifying and responding to human suffering. Have you practiced your own key phrases to elicit the human fears and sufferings of your patients? "I can only try to imagine how difficult this time must be for you and your family. How can we better help you?" See accompanying Box 47-1 (on page 1914) in which two nurse researchers outline the tenets of human

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

suffering. Remember, an analgesic will not "fix" human suffering. Your presence, however, has the power to comfort and heal. See Box 47-2 Steps for Being a Healing Presence on page 1914. A friend once wrote:

> *"…Here is the hardest thing I know: I am alone. The kind of alone that even having such good and plentiful friends can't fix. Ultimately alone. When they said, "You have cancer," they did not mean, "You and your friends have cancer" or just "You and your family have cancer." They meant "You, Laurie, have cancer." Well. Darn. I don't have much practice doing things alone. I don't have any desire either. I'm a team player. …Where's my "You have cancer" team? I looked around. The room was empty. They meant just me. …They say there is a pill for making the sad more tolerable. I'll take that pill, but I'll keep wishing for the one that makes being alone less lonely."*

Box 47-1 **Tenets of Suffering**

by Betty Ferrell and Nessa Coyle

- Suffering is a loss of control that creates insecurity. Suffering people often feel helpless and trapped, unable to escape their circumstances.
- In most instances, suffering is associated with loss. The loss may be of a relationship, of some aspect of the self, or of some aspect of the physical body. The loss may be evident only in the mind of the sufferer, but it nonetheless leaves a person diminished and with a sense of brokenness.
- Suffering is an intensely personal experience.
- Suffering is accompanied by a range of intense emotions, including sadness, anguish, fear, abandonment, despair, and myriad other emotions.
- Suffering can be linked deeply to recognition of one's own mortality. When threatened by serious illness, people may fear the end of life. Conversely, for others, living with serious illness may result in a yearning for death.
- Suffering often involves asking the question "why?" Illness or loss may be seen as untimely and undeserved. Suffering people frequently seek to find meaning and answers for that which is unknowable.
- Suffering often is associated with separation from the world. Individuals may express intense loneliness and yearn for connection with others while also feeling intense distress about dependency on others.
- Suffering often is accompanied by spiritual distress. Regardless of religious affiliation, individuals experiencing illness may feel a sense of hopelessness. When life is threatened, people may conduct self-evaluation of what has been lived and what remains undone. Becoming weak and vulnerable and facing mortality may cause a person to reevaluate their relationship with a higher being.
- Suffering is not synonymous with pain but is closely associated with it. Physical pain is closely related to psychological, social, and spiritual distress. Pain that persists without meaning becomes suffering.
- Suffering occurs when an individual feels voiceless. This may occur when a person is unable to give words to their experience or when their "screams" are unheard.

Spiritual Health and Healing

Defined most simply, **spiritual health**, or spiritual well-being, is the condition that exists when the person's universal spiritual needs for meaning and purpose, love and belonging, and forgiveness are met. O'Brien's conceptual model of spiritual well-being in illness (Fig. 47-2) identifies three empirical referents of spiritual well-being: personal faith, spiritual contentment, and religious practice. **Spiritual healing** is the movement toward integration, from brokenness to wholeness.

Box 47-2 **Steps for Being a Healing Presence**

Inasmuch as it's more art than science, you'll have your own ways of bringing healing presence into your life and the lives of others. Following is a rough order for how you might proceed.

1. Open Yourself

Begin not with the other person but with you. Become present to yourself in a way that is honest, insightful, and accepting. Open to your uniqueness, humanness, prejudices, brokenness, and wholeness. Do this by owning your life story, continually fathoming who you are in a holistic manner, and developing or using a support system to which you hold yourself accountable.

2. Intend to Be a Healing Presence

Be aware that the healing presence doesn't just occur out of the blue, you intentionally decide to be such a presence with another. Intend to promote healing in its many forms, while being understanding of yourself as you emerge in the day-to-day intricacies of this practice.

3. Prepare a Space for Healing Presence to Take Place

Clear a space to interact with the other or others, assuring as much privacy as possible and creating an atmosphere of calm. Prepare a space also within by placing yourself out of the way and clearing away your personal expectations for what the other should be or do.

4. Honor the One in Your Care

Approach those you accompany as people with dignity and worth. Show your regard for them by honoring their individuality, equality, humanness, separateness, and sacredness. Respect their natural and unique healing capacity.

5. Offer What You Have to Give

Freely and simply make available what you have to offer, realizing it is up to the other or others to accept or not. Offer presence, loving acceptance, empathy, dependability, an unselfish focus on them, your firm belief in them, your willingness to follow their lead, and, as much as anything, hope.

6. Receive the Gifts That Come

Accept with a grateful heart what is yours to receive. This may include living your life more fully as a result of this practice. Other gifts may include uncovering your genuine self, enjoying wonderful relationships, finding personal satisfaction, realizing you have made a difference, receiving your own healing, and exploring some of life's most valuable lessons.

7. Live a Life of Wholeness and Balance

There is more to life than being a healing presence. So, live your days fully, caring for your own needs, setting appropriate boundaries, encouraging your own growth, and nurturing a loving attitude toward life, including the sacred dimension. Affirm and live out the truth of the transforming potential of healing presence. Be grateful for the possibilities.

Spirituality and Everyday Living

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Spiritual beliefs and practices are associated with all aspects of a person's life, including health and illness. The major wisdom traditions address the invisible Spirit—a creative, mysterious guiding power—by creating principles and practices that:

- Cultivate love for ourselves, our neighbors, of a higher being, and of nature
- Cultivate wisdom that helps us find meaning in life; be in relationships with others; be true to ourselves; live in uncertainty and mystery; deal with suffering, sickness, and death; and honor life's transitions (birth, marriage, death)
- Cultivate awareness of the sacred dimension of life through practices such as worship, prayer, meditation, and singing (Fig. 47-3)
- Respect our connectedness as fellow human beings while acknowledging our differences
- Help us be generous in service to others

FIGURE 47-3. Members of a Gospel choir put their whole selves into a song. (Courtesy of Shutterstock.)

Religious influences may be life affirming or life denying. Life-affirming influences enhance life, give meaning and purpose to existence, strengthen a person's feelings of self-worth, encourage self-actualization, and are health giving and life sustaining. Life-denying influences restrict or enclose life patterns, limit experiences and associations, place burdens of guilt on people, encourage feelings of unworthiness, and are generally health denying and life inhibiting.

Spirituality, Health, and Illness

Spiritual beliefs are of special importance to nurses because of the many ways they can influence a patient's level of health, sense of well-being, and self-care behaviors.

Guide to Daily Living Habits

Certain practices generally associated with health care may have religious significance for a patient. For example, many religions have dietary requirements and restrictions. Acceptable birth-control practices are determined by some religious faiths, as are some types of medical treatments (refer back to Table 47-1).

Source of Support

Many people seek support from their religious faith during times of stress. This support is often vital to the acceptance of an illness, especially if the illness brings with it a prolonged period of convalescence or may lead to a questionable outcome. Prayer, devotional reading, and other religious practices often do for the person spiritually what protective exercises do for the body physically.

Box 47-3 **The Center Point That Grounds Us…**

I could scarcely make out the large sitting Buddha near the entrance of the house. But what caught my attention was the metal circle with spokes resembling a wheel, hanging over the Figure of the Buddha …. I asked our host about the wheel. I was told it represented our eternal journey in this life and continuing into the next. Buddha's teachings say that life is suffering. We cannot avoid suffering as we move around the rim of the wheel, which represents perpetual change and the transitory nature of life. But the wheel also symbolizes wholeness or completion because the wheel revolves around the center axis that does not move. That center point represents the presence of the divine. If we remain aware of this center point, we are strengthened for whatever lies ahead.

… It is this center point that grounds us in the midst of the many changes in our lives. It is at the center point where we experience the energy and power that turns the wheel. It is at this center point that we connect with the Everywhere Spirit. When we rest in the center point, we find that we have come home

again to the place from which we started. But because of the journey, it is as if we had arrived home for the first time. In our journey around the circles of life, we become new people over and over again.

Source: Reprinted with permission from Gregg-Schroeder, S. (1999). A transforming experience: Circles of life. *Journal of Fellowship in Prayer*, 23–25.

Think back to **Margot Zeuner**, the 75-year-old woman caring for her husband with advanced Alzheimer's disease. Assessment revealed that Mrs. Zeuner derived much support from her church group. The nurse, acknowledging the importance of this aspect, could work with Mrs. Zeuner to arrange for assistance at home so that she can attend church activities and continue to receive the support she needs. A referral to the church might also result in church members seeking out the Zeuners and offering assistance.

Box 47-3 describes how one religion, Buddhism, sees the divine grounding for all human experience, including suffering.

Source of Strength and Healing

The value of religious faith cannot be enumerated or evaluated easily. However, the effects attributable to faith are constantly in evidence to health care workers. People have been known to endure extreme physical distress because of strong faith. Patients' families have taken on almost unbelievable rehabilitative tasks because they had faith in the eventual positive results of their effort. In the Through the Eyes of a Patient box, a woman facing life-threatening events describes what she means by healing. She paints a robust vision of living fully, not in spite of illness, but rather because of it.

Source of Conflict

Sometimes religious beliefs conflict with prevalent health care practices (see Table 47-1 on pages 1911–1912). For example, the doctrine of the Jehovah's Witnesses prohibits blood transfusions. Some Navajos use a lengthy religious ceremony to cure certain diseases, such as tuberculosis. For some people, illness is viewed as punishment for sin and is therefore inevitable.

Such beliefs may require the health care worker to modify a treatment plan to accommodate the person's religion. In some instances, acknowledgment of the patient's religious convictions and efforts by health practitioners to accommodate the patient's beliefs can result in quality health care without violating the person's religious practices. In other situations, an objective explanation of alternative treatments and the predicted consequences of each may help the patient choose acceptable therapy. Whatever the person's decision about health care, remember that each person is unique and has a right to pursue their own convictions, even though they may differ from those of the health care provider.

Health care professionals can reduce conflict by attempting to understand how a particular religious culture influences people's thinking about basic questions of biology and ethics. Some of the major questions that religious beliefs, attitudes, and values can affect include:

- What is the meaning of suffering?
- How should we regard the physical body and its functions?
- What are the meaning and role of biologic sex differences, sexuality, and reproduction?
- How are we to understand and respond to birth, aging, and death?
- What constitutes the self, and how is selfhood assessed?
- How are sin and moral culpability understood? What makes something sinful, and how is sin relieved or absolved?
- What are the tradition's specific bioethical teachings?

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Remember **Choi Min Lai**, described at the beginning of this chapter. The nurse could use these questions to assess the family's beliefs in greater depth, providing significant data for the health care team to incorporate when discussing the possibility of surgery to repair Kou's deformities. Doing so could be helpful in minimizing the conflict between the family and health care team.

FACTORS AFFECTING SPIRITUALITY

Among the many factors that can influence a person's spirituality, the most important are developmental considerations, family, ethnic background, formal religion, and life events.

Through the Eyes of a Patient

Seven years ago, I was faced with three life-threatening events in a period of 3 years. Those life-threatening experiences taught me that it is possible to "heal" and to live fully even when we are in the abyss of suffering. I believe everyone would benefit if we redefined "healing." Here are elements I now include in my definition.

Healing is:

- Becoming whole, a life-long journey of becoming fully human, involving the totality of our being: body, mind, emotion, spirit, social, and political context, as well as our relationships with others and with the Divine. Healing does not necessarily mean being happy or getting what we think we want out of life; it means growth, often with pain.
- Becoming our authentic self, releasing old unreal self-images, discovering who we really are, not what we think we should be, knowing why we are here and what we really value, restoring our ability to heed our aspirations.
- Reconnecting lost aspects of ourselves, paying attention to buried feelings and places inside us that are distressed or sick, enabling us to express our self in fullness, both the light and shadow sides.
- Being open to change and new possibilities, responding to problems by changing the picture, being willing to let in more life, to open up to what may have been previously closed or destroyed for us and that which holds promise of giving us new life and fulfillment.
- Facing our fears and refusing to be injured or wounded, changing our belief systems, breaking unnecessary taboos, letting go of what is familiar, and stepping into the unknown.
- Accepting that problems, pain, and suffering are part of life and inseparable from us—not a peripheral relationship, not something isolated and avoidable—enabling us to enter into problems and use suffering, pain, and life-threatening events to enrich our lives.
- Being empowered by the Divine; discovering meaning in our defects, disorders, problems, and disease; experiencing new degrees of creativity and life forces that we might never have imagined before our difficulty; finding that our pains and fears are transformed into relief and confidence.
- Recognizing the value and preciousness of life, knowing that every moment is unique and significant, which usually leads to greater appreciation of the wonder of our minds, bodies, and spirits and of the Divine.
- Having faith and hope—important preconditions for mental and physical health; having a belief in the Divine, the meaning of human life, and the universe; helping us to claim our capacity to create and make something new.
- Finding inner peace, contentment, and tranquility amid the realities of daily life, including its problems, changes, and chaos; experiencing a sense of fullness that makes the burdens of pain or illness lighter.
- Being forgiving of ourselves and others and being forgiven; giving ourselves and others the freedom to let go of rivalry, strife, anger, hatred, fear, and limitations.
- Feeling connected to one another, a sense of interdependence; knowing we are not isolated or autonomous, giving up the illusions of boundaries in life; taking responsibility, acting justly, and accepting that we share our humanity.
- Being loving and loved; loving one's self and wanting to love and serve others, as well as being capable of receiving love; having an ability to trust, a feeling of aliveness, and a sense of greater participation in life.

Developmental Considerations

Because spirituality involves the nonmaterial realm of being, a child must have developed some capacity for abstraction in order to understand the spiritual self. However, this is not to say that spirituality is meaningless for children. For example, David Heller (1985) interviewed 40 children between 4 and 12 years old who were affiliated with one of four major religions (Judaism, Roman Catholicism, Protestantism, or Hinduism) and discovered that the children had definite perceptions of God. Central themes in all the children's descriptions included the following:

- Notion of a God who works through human intimacy and the interconnectedness of lives
- Belief that God is involved in self-change and growth and transformations that make the world fresh, alive, and meaningful
- Attributing to God tremendous and expansive power and then showing considerable anxiety in the face of this power
- Image of light

As the child matures, life experiences usually influence and mature the child's spiritual beliefs. With advancing years, the tendency to think about life after death prompts some people to reexamine and reaffirm their spiritual beliefs. Chapter 22 describes the stages of faith development.

Family

A child's parents play a key role in the development of the child's spirituality. What parents explicitly teach a child about spirituality and religion is generally less important than what the child learns about spirituality, life, and self from the parents' behavior.

Ethnic Background

Religious traditions differ among ethnic groups. There are clear distinctions between Eastern and Western spiritual traditions as well as among those of individual ethnic groups, such as Native Americans. A person's culture and formal religion significantly affect whether the person's approach to religion is doing something, being someone, or continually striving for harmony.

Formal Religion

Each of the major religious groups discussed earlier in this chapter shares several characteristics:

- Basis of authority or source of power
- Scripture or sacred word
- An ethical code that defines right and wrong
- A psychology and identity, so that its adherents fit into a group, and the world is defined by the religion
- Aspirations or expectations
- Ideas about what follows death

Life Events

Both positive and negative life experiences can influence spirituality, and they in turn are influenced by the meaning a person's spiritual beliefs attribute to them. For example, if two women who believe in a loving God both lose a child in a car accident, one may bitterly deny God's existence, whereas the other may spend more time in prayer, asking God to help her. Similarly, a chain of successful life experiences (marriage, promotion) may cause one person to assume success and experience no need for God, whereas for another it occasions deep gratitude and rejoicing.

Recall **Kevin Gargan**, who recently experienced a heart attack. The experience of his own mortality and the thought that he might have died now have him questioning whether there is a God and where he stands in relationship to God.

RELIGION AND LAW, ETHICS, AND MEDICINE

Christian Scientists, Jehovah's Witnesses, and members of certain faith-healing groups are among those challenging the

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

intricate web of rights and responsibilities that links people, society, church, and state. These religious bodies are asking for protection, under the umbrella of religious freedom, of the believer's right to exercise individual decisions in accordance with scriptural interpretations, even though those decisions may result in a person's own death or that of a family member, including a child. Most troubling are those cases in which treatable problems, such as bacterial meningitis, diabetes, or bowel obstruction, resulted in the death of minors whose parents choose religious means of healing over traditional medicine. (See Focused Critical Thinking Guide 47-1.) The American Academy of Pediatrics urges that all child abuse, neglect, and medical neglect statutes be applied without potential or actual exemption for religious beliefs.

Perhaps even more troubling for nurses are situations in which family members insist on painful care that is deemed medically futile (i.e., the likelihood of medical benefit is virtually nonexistent) because they believe that God is going to work a miracle. In these cases, simple nursing measures, such as turning or bathing patients, can become occasions of pain and torment to both the patient and nurse. Nurses are forced to administer care that they take to be cruel and abusive to patients capable of experiencing pleasure and pain. This nursing care can needlessly prolong a patient's painful dying. Unfortunately, there are no clear guidelines for drawing a line between promoting life and prolonging the dying process. Although nurses always have the moral right to withdraw from administering care that violates their personal moral code, this does not resolve the problem for the patient. More dialogue is needed on the interaction between religion and law, ethics, and medicine. Ideally, the religious freedom of patients and their families is respected, as is the moral autonomy of caregivers and the integrity of the healing professions. Nurses in these situations should seek the assistance of the ethics committee or ethics consultation service.

Consider the situation of **Choi Min Lai**, the father described at the beginning of this chapter. The nurse is required to respect the family's religious freedom and advocate for them while at the same time acting as a professional member of the health care team.

PARISH NURSING

Parish nurse programs are a relatively new movement in faith communities in many denominations. They seek to reclaim the church's role in the ministry of healing and focus again on the impact that spirituality, caring relationships, and a responsibly balanced life can have on health and wellness. Parish nurses (also called faith community nurses) and health ministry teams work to reintegrate the healing tradition into the life of faith communities by:

- Interpreting the relationship between faith and health
- Promoting personal responsibility for health and wellness
- Serving as health counselors and educators
- Staying aware of available resources and making appropriate referrals
- Acting as advocates for people who have health needs but only limited resources
- Recruiting and training volunteers
- Visiting church members
- Initiating caring relationships with older adults, the chronically ill, and the "worried well"

Parish nurses are not visiting nurses or home health care nurses who provide direct bedside care. The key roles of the parish nurse are health educator, personal health counselor, referral agent, trainer of volunteers, developer of support groups, integrator of faith and health, and health advocate. Nurses who wish to be parish nurses must be registered and compliant with both the state practice act and Faith Community Nursing: Scope and Standards of Practice (American Nurses Association, 2012). Check out the website of the Westberg Institute for Faith Community Nursing at http://www.parishnurses.org for more information on parish nursing.

47-1 Focused Critical Thinking Guide

Spirituality

A 16-year-old student approaches you, the schoolr nurse, and confides that she is worried about her brother, who is sick and getting sicker. "My parents are Christian Scientists and have had Christian Science Practitioners in to pray

for him, but he seems to be getting worse. I'm afraid he'll die if we don't get him to the hospital." Your first impulse is to visit the student's home to try to see her brother and parents. You immediately remember an article in the paper about the Supreme Court's decision to let stand a Minnesota Court of Appeals ruling upholding an award of $1.5 million to the father of a boy who died in 1989 after his mother, stepfather, and two Christian Scientist Practitioners tried to use prayer to heal his diabetes. Despite their efforts, the boy slipped into a coma and died. What is troubling you is the following comment by Stephen Carter: "By refusing to intervene in *McKown v. Lundman*, the Supreme Court has reinforced a societal message that has grown depressingly common: It is perfectly OK to believe in the power of prayer, so long as one does not believe in it so sincerely that one actually expects it to work—a peculiar fate indeed for our 'most inalienable' right" (Carter, S. L. [1996, January 31]. The power of prayer, denied. *The New York Times*, A17). You do believe in the power of prayer and are not sure how you should respond to the student's plea for help for her brother.

1. Identify goal of thinking

Clarify (1) what I believe about prayer's power to heal, and (2) what I believe about a parent's right to substitute prayer for modern medicine when a child is seriously ill. Decide how I should respond. What are my professional obligations?

2. Assess adequacy of knowledge

Pertinent circumstances: This is the first time I have encountered a family of Christian Scientists. As a school nurse, I am not responsible for my student's brother if he is not in my school and place of employment. That said, I have been asked to help and have the resources to do so.

Prerequisite knowledge: I have no knowledge of what Christian Scientists believe. Moreover, I do not know how the law in our state responds to situations like these. I do not know if any nursing or medical groups have guidelines for situations like these. I immediately get on the Internet to address these deficiencies and also contact my professional nursing organization to see what the law is and if any professional organizations have addressed this issue. I also have to find out how sick the student's brother is and the probable consequences of his not seeking traditional medical care.

Room for error: The student's brother's very life may depend on whether and how I choose to respond.

Time constraints: Until I learn the exact nature of the boy's medical problems, I cannot know how urgent the need to intervene is.

3. Address potential problems

In a situation like this, the most obvious impediments to critical thinking would be (1) the unexamined belief that religion trumps all other considerations ("by golly, this country is founded on respect for religious freedom") and (2) the belief that modern medicine is owed to everyone with a life-threatening illness, no matter what other considerations are present.

4. Consult helpful resources

I decide to visit the boy's home with the student and call first to seek the parents' permission. After talking with the parents and seeing the boy, I believe that the boy is in a life-threatening situation because the parents were told that their son has diabetes. I am struck by the love and devotion of both parents, and I learn via internet research that they are doing exactly what their religion prescribes. I later consult with a local Christian Scientist group that confirms this. I learn from my professional nursing organization that there is no consensus about how society should respond in situations like these. Many believe that what these parents are doing is neglect and that if the boy dies, they should be held criminally accountable for manslaughter. Others respect their right to practice their religion. Uncertain of how I should respond, I decide to call Child Protective Services and tell them that I am willing to help if they think my relationship with the daughter would be helpful. I explain to my student what I am doing and tell her to keep me informed and to come back for help if she is not getting the assistance she needs.

5. Critique judgment/decision

Child Protective Services did intervene immediately, and the boy was hospitalized and treated against the parents' wishes. While I was happy that the boy's condition was stabilized, I did feel uncomfortable about the disrespect shown to these obviously intelligent, devout, and loving parents. I decided to learn more about how different states are responding to these challenges and to see if nursing can get involved in some way.

NURSING PROCESS FOR SPIRITUAL HEALTH

Nurses who role model good health behaviors are more effective teachers. Many nurses approach professional practice

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

as more than a "job" and use the language of "sacred calling" or "vocation" to describe their career choice. Refer to the display, Promoting Health 47-1; use the assessment checklist for yourself before using it with others.

Assessing

Nursing History

Because a person's spirituality and religious beliefs can influence every aspect of being, an assessment of the patient's spirituality—including beliefs and practices, the effect of these beliefs on everyday living, spiritual distress, and spiritual needs—should be included in each comprehensive nursing history. However, nurses often need guidance in assessing spirituality in their patients, and in providing spiritual care; the accompanying Research in Nursing box highlights two studies related to spiritual care. Many guides are available for eliciting a spiritual history, such as those from O'Brien (1982), Shelly and Fish (1988), and Puchalski and Romer (2000). One simple guide is Anandarajah and Hight's (2001) HOPE acronym:

- **H—**Sources of **H**ope, meaning, comfort, strength, peace, love, and connection
- **O—O**rganized religion
- **P—P**ersonal spirituality and practice
- **E—Ef**fects on medical care and end-of-life issue

Sample questions are listed in the Focused Assessment Guide 47-1.

If the patient reveals a spiritual problem, use interview questions to determine the specific nature of the problem, its probable causes, its related signs and symptoms, when it began and how often it occurs, how it affects everyday living, its severity and whether it can be treated independently by nursing or needs to be referred, and how well the patient is coping.

Think back to **Kevin Gargan**, the man who experienced the heart attack. The nurse could use the questions in the Focused Assessment Guide to determine Mr. Gargan's beliefs and thereby develop a care plan that addresses his current needs. In addition, this assessment would provide valuable information about how the patient is coping with the current situation.

Nursing Observation

Because many patients find it difficult to talk about their spiritual beliefs and problems, also observe the patient's behavior for signs of spiritual distress. A family member or close friend may share significant observations:

- "He's been awfully moody since his heart attack. I can't believe how hopeless he seems now."
- "I've never seen my father so depressed. He's never in his life been away from the synagogue at Passover. I don't know how to help him."

Promoting Health 47-1

SPIRITUALITY

Use the assessment checklist to determine how well you are meeting your spirituality needs. Then develop a prescription for self-care by choosing appropriate behaviors from the list of suggestions.

Assessment Checklist

☐ almost always ☐ sometimes ☐ almost never

☐	☐	☐	1. I am comfortable with my spiritual beliefs and values.
☐	☐	☐	2. My beliefs meet my needs for love and belonging, forgiveness, and meaning and purpose.
☐	☐	☐	3. I respect the belief systems of others.

☐ ☐ ☐ 4. I derive sufficient strength from my religious beliefs to meet each day's challenges, especially when confronting pain, suffering, and death.

Self-Care Behaviors

1. Explore personal values and beliefs of self and others.
2. Set aside regular periods to nurture spiritual self.
3. Explore practices that are spiritually supportive.
4. Demonstrate in interaction with others peace, inner strength, warmth, joy, caring, creativity.
5. Respect the belief systems of others.
6. Practice loving relationships with self and others.
7. Seek spiritual assistance to help cope with stress, crisis, or loss.

Research in Nursing

Bridging the Gap to Evidence-Based Practice

Critical Care Nurses' Perceived Need for Guidance in Addressing Spirituality in Critically Ill Patients

The term *spirituality* is defined in different ways by different people. No common or universally accepted definition for the term exists.

Related Research

Canfield, C., Taylor, D., Nagy, K., Strauser, C., VanKerkhove, K., Wills, S., Sawicki, P., & Sorrell, J. (2016). Critical care nurses' perceived need for guidance in addressing spirituality in critically ill patients. *American Journal of Critical Care*, *25*(3), 206–211. https://doi.org/10.4037/ajcc2016276

The researchers interviewed 30 nurses who worked in a critical care unit at a large Midwestern teaching hospital. Their objectives were to examine individual critical care nurses' definitions of spirituality, their comfort in providing spiritual care to patients, and their perceived need for education in providing care. They found that nurses generally feel comfortable providing spiritual care to critically ill patients but need further education about multicultural considerations. Nurses identified opportunities to address spiritual needs throughout a patient's stay but noted that these needs are usually not addressed until the end of life.

Ernecoff, N. C., Curlin, F. A., Buddadhumaruk, P., & White, D. B. (2015). Health care professionals' responses to religious or spiritual statements by surrogate decision makers during goals-of-care discussions. *JAMA Internal Medicine*, *175*(10), 1662–1669.

Researchers recorded conversations between health care professionals and patient surrogates to determine how frequently religion and spirituality were discussed, by whom, and with what responses. Of 249 analyzed conversations, discussions of religion or spirituality occurred in 40 (16.1%), and the surrogates raised the subject in 26 of those (65%). In only eight conferences did health care professionals ask questions in response to the raised religious issues to gain deeper understanding. More often they switched the conversation back to medical issues. The study authors concluded, "It may be that clinicians do not know how to navigate these conversations or that they were taught to avoid discussion of such topics in favor of prioritizing discussions of medical facts."

Relevance for Nursing Practice

Clearly, more guidance must be offered to nurses and other health care professionals about how to recognize and respond to spiritual needs. Evidence-based interventions coupled with clear standards of care that hold nurses accountable for meeting spiritual needs and promoting spiritual health are needed. This research is still in its infancy.

Focused Assessment Guide 47-1

SPIRITUALITY

Factors to Assess	Questions and Approaches
Spiritual beliefs	"Are there particular spiritual or religious beliefs that are important to you? Have these beliefs changed recently? Is your illness challenging these beliefs? Do your religious beliefs in any way dictate a course of action that puts you in conflict with what your health care providers are recommending?"
Spiritual practices	"Describe your usual spiritual practices and anything interfering with your ability to perform them. Can I help in any way to secure the aids necessary for these practices (prayer shawl, Bible, crystals, amulets, beads, icons)?"

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Relation between spiritual beliefs and everyday living	"Describe ways your spiritual beliefs affect everyday living (daily schedule, diet, hygiene, sense of self and the world, relationships). Do you find this influence to be healthy (life affirming) or destructive (life denying)?"
Spiritual deficit or distress	"Are your spiritual beliefs currently causing you any distress?"
Spiritual needs	"In what ways can I and the other nurses help you to meet your spiritual needs?" "Would you like me to contact your spiritual advisor or the hospital's pastoral care minister?"
Need for meaning and purpose	"In what ways do your religious beliefs help or hinder you to understand your current situation and face it with peace and courage?"
Need for love and relatedness	"In what ways do your religious beliefs help or hinder you to meet your need to love and be loved?"
Need for forgiveness	"In what ways do your religious beliefs help or hinder you to feel at peace?"
Significant behavioral observations	Be alert to sudden changes in spiritual practices, mood changes, sudden interest in spiritual matters, and sleep disturbances—any of which may point to unresolved spiritual needs.

Significant behavioral observations include sudden changes in spiritual practices (rejection, neglect, fanatical devotion), mood changes (frequent crying, depression, apathy, anger), sudden interest in spiritual matters (reading religious books or watching religious programs on television, visits to clergy), and disturbed sleep. If you observe these behaviors, you should follow up with appropriate interview questions.

"Often, problems with spiritual distress do not surface until well after a patient's diagnosis of serious illness." This would be applicable in a home as well as hospital setting. Effective questions include the following:

- "You've been lying there so quietly. What are you thinking about?"
- "After all you've been through, you must have done a good bit of soul searching. Experiences like these are enough to shake anyone's faith—how is yours holding up?"

Diagnosing Actual or Potential Health Problems and Needs

An assessment of a patient's spirituality and spiritual health may lead to the identification of one or more actual or potential health problems and needs related to spirituality. Following the formulation of the actual or potential health problems and needs, the nurse communicates findings to other nursing and health care professionals through the use of the written and spoken word. The written actual or potential health problem or need becomes a permanent part of the patient's health record.

The International Classification for Nursing Practice (ICNP) identifies several actual or potential health problems that may be identified by nurses:

- Impaired Spiritual Status
- Spiritual Distress
- Suffering
- Risk for Conflicting Religious Belief

Spiritual distress may be further specified as spiritual pain, alienation, anxiety, guilt, anger, loss, or despair (O'Brien, 1982). Common etiologies for spiritual distress include inability to reconcile a current life situation (e.g., illness, death of loved person, divorce) with spiritual beliefs ("God is all-powerful, all-loving, all-wise, and He cares about me") or separation from the religious community or supports. Common etiologic factors and potential signs and symptoms for some of these health problems are found in the accompanying box, Examples of Actual or Potential Health Problems and Needs: Spiritual Distress.

Outcome Identification and Planning

Enhancing Spiritual Health

Show you value spiritual health by being sensitive to the role that spiritual beliefs play in influencing both a person's thoughts about self and the world and their interactions with the world. Your interactions with any patient who values spirituality support the following patient outcomes.

The patient will:

- Identify spiritual beliefs that meet needs for meaning and purpose, love and relatedness, and forgiveness
- Derive from these beliefs strength, hope, and comfort when facing the challenge of illness, injury, or other life crisis
- Develop spiritual practices that nurture communion with inner self, with God or a higher power, and with the world
- Express satisfaction with the compatibility of spiritual beliefs and everyday living

Addressing Spiritual Distress

Goals and expected outcomes for patients in spiritual distress need to be individualized and may include a patient achieving some of the following:

- Exploring the origin of spiritual beliefs and practices
- Identifying factors in life that challenge spiritual beliefs
- Exploring alternatives given these challenges: denying, modifying, or reaffirming beliefs; developing new beliefs
- Identifying spiritual supports (e.g., spiritual reading, faith, community)
- Reporting or demonstrating a decrease in spiritual distress after successful intervention

Implementing Spiritual Care

A variety of interventions are available to help patients meet their spiritual needs. Like other nursing skills, these interventions need to be practiced before they can be used confidently, competently, and at the right moment. These interventions can be used in the home, hospital, or care center to help patients meet their spiritual needs. When implementing spiritual care, nurses work closely with other spiritual caregivers, including chaplains and pastoral care workers. Often the most important intervention is a well-timed referral to a professional spiritual caregiver.

Ethical and Professional Boundaries

Before exploring spiritual care strategies, remind yourself of the importance of discussing spiritual concerns in a respectful manner and as directed by patients. While the PEW landmark religion survey shows the importance of religion to many Americans, it is also true that religion means very different things to different people. A nurse's offer to pray for a patient may be received gratefully by one person and dismissed angrily by another who associates prayer with a "last resort" intervention when everything else has failed. The fact that some health care professionals confuse spiritual care with proselytizing (trying to convert others to their own religion) is another source of concern. Puchalski (2006) offers the following hints about professional boundaries:

- Keep the spiritual history patient centered.
- Recognize pastoral care professionals as experts in this field and consult them appropriately.
- Proselytizing is never acceptable in professional settings. Addressing spiritual issues should not be coercive.
- More in-depth spiritual counseling should be under the direction of chaplains and other spiritual leaders.
- Praying with patients should not be initiated by the nurse unless there is no pastoral care available and the patient requests it, or in situations in which the nurse and patient have a long-standing relationship or share a similar belief system. The nurse can stand in silence as the patient prays in her or his tradition. The nurse can always make a referral to pastoral care for chaplain-led prayer.

Examples of Actual or Potential Health Problems and Needs

SPIRITUAL DISTRESS

Actual or Potential Health Problems and Needs	Possible Etiologic Factors	Potential Signs and Symptoms
Spiritual Pain	Inability to accept death of son	A 46-year-old woman, agnostic, only son died 6 months ago (lung cancer) "I've often wondered throughout my life if there is a God—thought maybe if I had tried harder, I'd have recognized him. Now, I don't care if God exists or not because if he allows this, I don't want to know him." "My son was my whole life; there's nothing left for me to live for." Lost 10 lb in 6 months since son died; leaves home only when necessary to purchase food, go to bank, and engage in other routine activities.
Spiritual Alienation	Separated from "faith community"	A 72-year-old Orthodox Jewish man, recently admitted to Protestant long-term care facility following 3-week hospitalization for stroke "I guess Yahweh has written me off; first the stroke that killed half my body and then I'm abandoned here where I can't

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

		even observe the Sabbath." "I want to go home."
Spiritual Anxiety	Challenged belief and value system	A 37-year-old previously healthy executive recovering from massive myocardial infarction "My parents were strict Methodists, but when I left home for college, I stopped going to church … never gave it much thought … there was always something else to do. I started going again but it never meant much." "I haven't exactly done anything awful, but I've also not been a saint and I find myself wondering if there is a God, what does he think of me." "Funny, I guess I thought I'd live forever. I sure never thought about dying and what happens after that." Often observed lying quietly in bed awake; asked to see minister.
Spiritual Guilt	Failure to live according to religious rules	A 23-year-old, single, Baptist woman being treated for premenstrual syndrome "I was raised in a strict Baptist home but had to leave … I needed more room to be me. I like life here at the university but there's a restlessness in me I can't describe. I've dated several men, one or two I really liked, but I always do something to mess up the relationship. It would kill my mother if she knew I lived with Gary for 3 months." "What it really comes down to is my own sense of betraying myself, my family, and my religion. Who am I anyway?"
Spiritual Anger	Inability to accept illness	A 38-year-old gay man recently diagnosed with AIDS "My parents are fundamentalists … all I ever heard at home was how much Jesus loves me … all the while my mom was beating the daylights out of me…. Does He love me? Does He love me so much that He had my parents throw me out when I finally told them I was gay? Does He love me so much that I got AIDS and now no one comes near me?" Facial features are tight; body held rigidly; speech is sharp, appears angry with God, the world, himself.
Spiritual Loss	Terminal illness; anticipatory grieving; inability to find comfort in religion	A 40-year-old mother of three sons who was diagnosed with ovarian cancer 18 months ago; currently in advanced stage of disease "I've tried hard to do it all right … I read my Bible, prayed every day, went to church each Sunday, loved my husband and kids … why is this all happening to me? Why must I lose it all? Where is God now that I need

		him? Some mornings I wish I could shoot myself and end it all—instead another day drags on. Who can help me?” Cries frequently, no longer interested in everyday activities of family, no interest in praying, told family not to have pastor call anymore. “No one can help now.”
Spiritual Despair	Feeling that no one (not even God) cares	A 92-year-old frail widow who lives alone in a two-room apartment; crippled with arthritis; has two married sons she has not seen for years. Says to community nurse who visits every week, “No one should have to live like this. If it weren’t for the neighbor who comes on Saturday with a few groceries and you, I’d be dead. I guess that would be for the best. It’s been a long time since I felt like my living or dying would matter to anyone. Because I’m 92 now, I guess even God doesn’t want me. Couldn’t you do something to put me out of my misery?”

Source (for Actual or Potential Health Problems or Needs): O’Brien, M. E. (1982). The need for spiritual integrity. In H. Yura, & M. B. Walsh (Eds.). Human needs and the nursing process (pp. 81–115). Appleton-Century-Crofts.

Offering Supportive or Healing Presence

A nurse’s gift of supportive presence must underlie all other types of intervention to meet the patient’s spiritual needs. The aim of this intervention is to create a hospitable and sacred space (“holy ground”) in which patients can share their vulnerabilities without fear. Supportive presence communicates value and respect (Fig. 47-4). Chapter 8 presents basic communication skills helpful in establishing this type of presence. Box 47-3 (on page 1916) outlines helpful steps for nurses who are intent on developing the art of healing presence. Never was presencing more important than during the COVID-19 pandemic. Patients with COVID-19 who were admitted to the hospital were often allowed no visitors and nurses helped facilitate communication with families using smartphones or social media. Too often, the only person present to a dying patient was a nurse, a nurse newly valuing their ability to be present in a respectful, affirming way.

The patient who senses that the nurse is sincerely concerned and committed to helping meet human needs is better able to participate in the care plan. Patients who experience respect and affirmation from other humans find it easier to hold spiritual beliefs that meet their needs for meaning and purpose, love and relatedness, and forgiveness.

FIGURE 47-4. The nurse offers supportive presence by holding the patient’s hand to show sincere concern, or simply by being present to communicate value and respect.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Facilitating the Practice of Religion

Ways that the nurse can help the patient continue normal spiritual practices in the unfamiliar environment of the hospital or care center are as follows:

- Familiarize the patient with the pastoral and religious services and materials available within the institution.
- Respect the patient's need for privacy or quiet during periods of prayer.
- Assist the patient to obtain devotional objects and protect them from loss or damage.
- Arrange for the patient wishing to receive the sacraments to do so.
- Attempt to meet the patient's religious dietary restrictions.
- Arrange for the patient's minister, priest, healer, or rabbi to visit if the patient so wishes.

If the patient has a conflict between spiritual beliefs and the proposed medical therapy, assist the patient in discussing this with the health care provider. For ill patients in the home who cannot attend services or meetings to which they are accustomed, help them find ways to meet their spiritual needs.

Nurturing Spirituality

Some patients who experience a need to get in touch with their spiritual self and to nurture their spiritual development look to the nurse for direction. Someone who lives life enmeshed in the action and noises of society may feel strange and uncomfortable when illness forces introspection. Be helpful by recommending methods a person might use to develop a relationship with their own inner world (such as prayer, reflection, dream analysis, nature walks, enjoying art) and ways to manifest spiritual energy in the outer world (such as loving relationships, compassion, forgiveness, joy, service).

Spiritual nurturing for the patient's family caregivers is also important. Recent research findings support the importance and value of caregivers' spirituality, yet this resource is often overlooked. Consider using interventions that enhance a caregiver's ability to take part in church activities to satisfy spiritual needs and to work with church groups to secure helpful services. Using clergy, prayer, forgiveness, and spiritual reading materials as resources for caregivers may also be helpful.

Knowledge of the supportive services provided by the church group of **Mrs. Zeuner**, the 75-year-old woman taking care of her husband with advanced Alzheimer's disease, would be important to include in the care plan for Mrs. Zeuner and her husband. Supportive services, such as respite care, parish nursing, and meals, in addition to the emotional support provided by the group, could be extremely helpful for Mrs. Zeuner in her role as caregiver.

Nurse Self-Care Alert

Finally, remember that, as nurses, we cannot give what we do not have. Unless our own spiritual needs are met, we will never be able to be truly present to another. Thus, the art of being a healing presence requires a lifestyle that supports our being a healing presence. Reflect on this proverb: *A happy heart is like good medicine. But a broken spirit drains your strength (dries your bones).—Proverbs 17:22*

The nurse can help patients to nurture their own spirituality by promoting meaning and purpose, love and relatedness, and forgiveness.

PROMOTING MEANING AND PURPOSE

In the book *Man's Search for Meaning,* psychiatrist Victor Frankl, who survived the horrors of the Nazi concentration camps, writes, "Once an individual's search for meaning is successful, it not only renders him happy, but also gives him the capability to cope with suffering" (1985, p. 163). To help patients searching for meaning, explore with them what has given their life meaning and purpose up to the present, sources of meaning for other people, and possible meanings for patients' current experience of illness, pain, suffering, or impending death. If a patient desires, arrange

for referral to a spiritual advisor. Explore with patients some spiritual practices that may give them strength and hope (e.g., prayer or reading scripture or other spiritual books). You might also want to recommend that patients read spiritual biographies or Harold Kushner's book When Bad Things Happen to Good People (1983), Kathleen Brehony's book *After the Darkest Hour: How Suffering Begins the Journey to Wisdom* (2000), Oliver Sack's Gratitude (2015), or Dr. Paul Kalanithi's *When Breath Becomes Air*. Referring patients to appropriate support groups (e.g., self-help groups for people with stroke, cancer) also is helpful.

PROMOTING LOVE AND RELATEDNESS

First and foremost, always treat the patient with respect, empathy, and genuine caring. Encourage the patient to talk about relationships with others and to identify the origin of any negative beliefs about people. Box 47-4 may be a good starting point for reflection on loving kindness.

Box 47-4 Loving Kindness Meditation

May you be at peace.
May your heart remain open.
May you awaken to the light of your own true nature.
May you know the power of your higher self.
May peace of mind be your only goal and forgiveness your only task.
May you be healed of all pain and hurt.
May you be a source of healing for others.
May you know the inner beauty of the person you truly are.
May you be at peace.

Source: unknown.

Encourage conversation about how a patient experiences God or a higher being if that is part of the patient's spiritual beliefs. If appropriate, introduce or reinforce the belief that God is a loving and personal God who is concerned about the patient. Whenever possible, encourage and facilitate visits from the patient's family, friends, and spiritual advisor.

PROMOTING FORGIVENESS

Offer a supportive presence to the patient that demonstrates your acceptance of the patient. Explore with the patient the importance of learning to accept self and others, including both strengths and limitations. Explore negative feelings that make it difficult for the patient to seek forgiveness and to believe that he or she is forgiven.

Explore the patient's self-expectations and assist the patient to determine how realistic these are. Allow the patient to verbalize shame, guilt, and anger, and counsel about the importance of expressing negative emotions in healthy ways. Refer the patient to a spiritual advisor, if appropriate. Offer the patient examples of how not forgiving others can end up hurting only the person who cannot forgive.

The Spiritual Needs of Younger Generations

Younger generations, such as Millennials, Millennials are less religiously affiliated than ever before. See the 2012 Pew Research Center report, "Nones on the Rise," which reports that nearly 1 in 3 millennials do not belong to a faith community, and, of those, only 10% are looking for one. This is especially troubling when we consider that rates of isolation, loneliness, and depression continue to rise and that suicide is the third leading cause of death among youth (Centers for Disease Control and Prevention, 2020). All of this, of course, was exacerbated during the COVID-19 pandemic. The Thurston-ter Kuile study, "How We Gather," notes that millennials are flocking to a host of new organizations that deepen community in "ways that are powerful, surprising, and perhaps even religious." The six themes central to their study of 10 organizations meeting the needs of millennials are

- Community
- Personal transformation
- Social transformation
- Purpose finding
- Creativity
- Accountability

Thurson-ter Kuile ask a formative question:

> What does it mean to touch the world in 2015? This is a moment when Brene Brown's TED Talks on vulnerability and Taylor Swift's random acts of kindness go viral. It's a moment when virtual connectivity is more immediate

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

than the "real" world, so that an American millennial feels more comfortable setting up a Kiva loan to a farmer in Kenya than bringing chicken soup to a neighbor. Is it possible to harness these new tools of global engagement to deepen our everyday experience of community as well?

If you belong to a traditional religion, have you reflected on the ways our changing generations and culture meet universal spiritual needs? You may also want to check out the Sacred Design Lab (Box 47-5). Learning that a patient does not claim membership in a traditional religion does not mean that they have no spiritual needs.

Box 47-5 **Sacred Design Lab**

Sacred Design Lab is a soul-centered research and development lab devoted to understanding and designing for 21st-century spiritual well-being. We translate ancient wisdom and practices to help our partners develop products, programs, and experiences that ground people's social and spiritual lives.

We envision a world in which every person is connected to their inherent goodness, known and loved in communities of care, and bountifully giving their gifts toward beauty, justice, and wholeness.

And yet, interlocking systems of oppression pull us apart. Unmet needs for meaning and connection play out in the way we live, love, work, and lead. The problem is soul-deep. So too must be our response.

Our Approach

Belonging
Knowing and being known, loving and being loved.

We belong to each other. The experience of belonging changes the way we show up, stimulating loyalty, compassion, and joy, and diminishing anxiety, loneliness, and fear. But belonging is not a passive state. It's something we nurture, express, renew, savor, and pass down. So much in our culture works against us meeting our need for deep connection: to ourselves, other people, place, story, and time. The more we reclaim the power of knowing, loving, and caring for one another, the more our hearts open and our society heals.

Becoming
Growing into the people we are called to be.

We each carry gifts the world needs. Yet too many of us face barriers to tending our inner gifts, sharing them in community, and bountifully receiving the gifts of others. To design for becoming is to disrupt productivity culture. It means listening for where we are each needed, addressing what stands in the way of our shared growth, and cultivating each other's courage to say "yes" to the soul's call. Soul-centered design fuels collective becoming.

Beyond
Experiencing ourselves as part of something more.

When our soul is fed, we remember that we are bound up in something larger than ourselves. Stretching across generations, ineffable and yet as solid as the ground, this is the larger story of which we are a part. What would it take to create a rhythm of life in which we have space in our days to feel fully big and fully small? When we design for the soul, we create pathways to move closer to the beyond, to the endlessly renewable resource at the heart of all things.

Ancient Wisdom, Emergent World
Applying ancient practices to emergent challenges.

How do we meet the needs of the soul and move toward flourishing? Luckily, humans have been responding to this question all over the world for thousands of years. Their wisdom is our collective inheritance. Now our work is to apply it, while honoring the origins and custodians of these traditions. We tap into ancient best practices to design for belonging, becoming, and beyond, and we work with partners to remix the wisdom of our ancestors to create soul-centered solutions.

Collective Liberation
Never forgetting that justice is what love looks like in public.

We long for a world in which every person is cared for and free from oppression. Without love as our means, and commitment beyond our self-interest, we can't build the resolve to dismantle systems of domination. Collective liberation is more than something we think; it's something we do. So we commit ourselves to constant learning, reflection, action, and practice. Refusing to use shame as a strategy, we invite our partners to lead with justice-seeking love, that all might

	flourish.
Means and Ends Cohere How we are together shapes what we do together.	We envision a world of justice, beauty, healing, and wholeness. Though interlocking systems of oppressions impact us differently, they keep all of us from fully living in that world. To design products, programs, and experiences that meet the soul's needs, our means must themselves be soul-centered. We center relationships even as we focus on outcomes, reject grind culture, and embrace our justice commitments. We show up with joy, integrity, and care.
Witness the Meantime Holding space for all that emerges.	This work is not easy. Our culture devalues presence, patience, kindness, and care. Few opportunities exist for lament, atonement, and reconciliation, despite long histories of suffering. Deepening meaning and connection takes courage, perseverance, and trust. We accompany the leaders we work with through the inevitable challenges of soul-centered work, drawing on practices of witness and reflection to encourage and embolden them.

Praying With Patients

Patients accustomed to regular periods of prayer but who feel too ill to pray as they would like or who enjoy praying with others may ask the nurse to pray with them or hope that the nurse will suggest this. Because there are many forms of prayer—quiet reflection, silent communion with God or a higher power, reading or recitation of formal prayers, silent or loud calling on God or a higher power or conversation with God or a higher power, lamentations, or reading a holy book or other religious materials—the nurse can take the lead from the patient by asking, "How would you like us to pray?" Consider the patient's religious background along with the type of prayers that have been meaningful in the past. Ask whether the patient has a particular prayer request.

A nurse unaccustomed to praying aloud or in public may find it helpful to have a Bible passage or formal prayer readily available. The prayer may also be a simple expression aloud of the patient's needs and hopes. A sample follows:

> Lord God, our Creator and Healer, I entrust Mrs. Smith and her family to your loving care. Bring peace to her mind and health and strength to her body. Be with her [as her treatment begins today, as she goes for surgery, and so on]. We remember all your blessings to us in the past and thank you. We are confident of your help now as we claim your promises.

Prayer should not block communication with the patient. Praying before a patient feels ready to pray may communicate to the patient a lack of interest in the patient's feelings. Because prayer often evokes deep feelings, the nurse should be prepared to spend time with the patient after sharing prayer to respond to these feelings.

Praying for Patients

With research suggesting links between prayer and physical, mental, and spiritual health, some have argued that health care professionals should pray for, as well as with, their patients. At the present time, no one is claiming that health care professionals are negligent if they fail to pray for patients. Prayer may, however, be an effective intervention strategy. At the very least, nurses ought to be mediators of the spiritual resources patients and their families need.

Counseling Patients Spiritually

The patient who feels that the nurse is sensitive to spiritual needs and comfortable with their own spirituality may choose to share spiritual concerns with the nurse rather than with a religious counselor. A nurse who feels competent to counsel the patient may assist the patient to accomplish the following:

- Articulate spiritual beliefs.
- Explore the origin of the patient's spiritual beliefs and practices.
- Identify life factors that challenge the patient's spiritual beliefs (cause spiritual distress).
- Explore alternatives given these challenges (e.g., modify lifestyle; deny, modify, or reaffirm beliefs; develop new beliefs).
- Develop spiritual beliefs that meet needs for meaning and purpose, care and relatedness, forgiveness.

To be an effective spiritual counselor, the nurse must be open to different spiritual beliefs and forms of spiritual expression and should be supportive of the patient's efforts to nurture spiritual growth.

Contacting a Spiritual Counselor

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Not every nurse feels comfortable in the role of spiritual counselor. If you do not, suggest that the patient talk to a pastoral caregiver or spiritual counselor. When a patient expresses a desire to speak to a spiritual counselor, help make the appropriate referral or offer to contact the patient's own spiritual advisor. Other options are to contact the health care facility's pastoral ministry department or use a referral list of clergy in the local community. If no representative of the patient's own religion can visit in the hospital at a particular time, suggest a visit from a member of the clergy from another faith. The patient, depending on the situation and the immediacy of the need, may welcome such a suggestion.

In a health care setting, you can assist the spiritual counselor by making the counselor feel welcome, directing the counselor to the patient, and ensuring that the patient is ready to receive the counselor. Preparations of the patient's room for the visit may vary, but the following are generally recommended practices:

- The room should be orderly and free of unnecessary equipment and items.
- There should be a seat for the religious counselor at the bedside or near the patient so that both can be comfortable. Ideally, the room will allow a private conversation.
- The bedside table should be free of items and covered with a clean, white cover if a sacrament is to be administered.
- The bed curtains should be drawn for privacy if the patient can't be moved to a more private setting.

Some patients and spiritual advisors may value the nurse's participation in prayers, rituals, or the administration of sacraments. By having good working relations with chaplains and pastoral caregivers, you can quickly direct them to patients most likely to benefit from their visits.

Resolving Conflicts Between Spiritual Beliefs and Treatments

Both the patient and members of the patient's family may experience conflict between a particular spiritual belief or religious law and a proposed medical treatment or health option. The patient may want assistance when conferring with the spiritual advisor about a particular procedure. The nurse's role is to help the patient obtain the information needed to make an informed decision and to support the patient's decision making. Because what the nurse says and the way it is said may powerfully influence the patient's decision, it is important to maintain objectivity. Conflicts that resist resolution may be referred to an ethics committee or consult team (see Chapter 6).

Nursing, Religion, and Conscientious Objection

In recent years, some pharmacists attracted media attention by refusing to fill prescriptions for contraceptives. These pharmacists supported their refusals by claiming that fulfilling such a prescription would violate their religious beliefs and convictions. In this situation, the woman's right to access medications is pitted against the pharmacist's right to practice with personal integrity. Nurses can also find themselves in situations in which their professional or institutional responsibilities involve participation in activities, such as abortion, assisted suicide, and counseling about birth control, that may violate their personal integrity. Nurses therefore must ensure that they can fulfill the responsibilities of their job or that they are free to exercise the right of conscientious objection. As legislation addressing these conflicts is in a state of flux, you should be familiar with federal and state guidelines. For example, in September of 2011, the University of Medicine and Dentistry of New Jersey announced that all nurses employed in its hospital would have to help with abortion patients before and after the procedure, "reversing a long-standing policy exempting employees who refuse based on religious or moral objections." After a group of objecting nurses filed a federal lawsuit, the hospital backed down, agreeing that nurses with conscientious objections do not have to assist with pre- or postoperative care for abortions except when the mother's life is threatened and no other nonobjecting staff are available to assist (Galston & Rogers, 2012, p. 1).

Evaluating

The nurse working with a patient and family to achieve specified goals or outcomes to meet spiritual needs evaluates the care plan in each patient interaction. Necessary to the evaluation are sensitivity to what the patient is saying and not saying, and observation of the patient when alone as well as when interacting with the family and nurses.

In general, the nurse evaluates the patient's ability to accomplish the following:

- Identify some spiritual belief that gives meaning and purpose to everyday life
- Move toward a healthy acceptance of the current situation: illness, pain, suffering, impending death
- Develop mutually caring relationships
- Reconcile any interpersonal differences causing the patient anguish
- Verbalize satisfaction with their relationship with God or a higher being (if important to the patient)
- Express peaceful acceptance of limitations and failings
- Express the ability to forgive others and to live in the present
- Demonstrate an "interior state of peace and joy; freedom from abnormal anxiety, guilt, or a feeling of sinfulness; and a sense of security and direction in the pursuit of one's life goals and activities" (O'Brien, 1982, p. 98)

The nurse helps the patient to determine whether their spiritual beliefs are generally life affirming or life denying, and whether there is harmony between these beliefs and the patient's everyday life experiences. See Nursing Care Plan 47-1 for Mr. Gargan on pages 1929–1930.

REFLECTIVE PRACTICE LEADING TO PERSONAL LEARNING

Remember that the object of reflective practice is to look at an experience, understand it, and learn from it. As you begin to develop your expertise in identifying and responding to spiritual needs, reflect on your experiences—successes and failures—in order to improve your practice. Universal spiritual needs, shared by all humans, are to find meaning and purpose, love and relatedness, and forgiveness.

- Have you encountered patients or their family caregivers whose spiritual needs are unmet?
- If you identified such needs, did you feel confidant and comfortable responding to these needs?
- Have your care plans ever identified and addressed spiritual needs?
- Are you familiar with the spiritual health resources, including professional spiritual caregivers, available in your practice settings?
- Have you tried to learn more about these members of the interprofessional team and how you can develop collaborative relationships that will best serve your patients?
- Have you ever consulted with a professional spiritual caregiver?

Perhaps the most important questions to reflect on are: Are your patients and their families/caregivers better for having had *you* share in the critical responsibility of partnering with them to respond to their spiritual needs? Are your patients now receiving thoughtful, person-centered, prioritized, holistic, evidence-based treatment and care because of your efforts?

Nursing Care Plan for Mr. Gargan 47-1

Mr. Gargan is a 38-year-old divorced man on a step-down unit after treatment for a myocardial infarction. He owns a small car dealership. His religion is listed as Protestant. Frequently unable to sleep at night, Mr. Gargan often talks with the night nurse, and once asked, "Did you ever give much thought to whether or not there is a God?" Sensing much concern behind this question, the nurse asks specific questions to determine whether the patient has spiritual needs that are not being met.

12/26/25, 0200

Patient again unable to sleep and initiated discussion about God. States that he was raised in a Lutheran home where everyone went to church on Sunday and tried to live according to God's commandments. Upon leaving home, he stopped going to church (was never a value for his wife) and simply has not given much thought to religion—too busy running his business. Until now, has not experienced any need for God. "But when I think how close I was to dying and that I've no idea what to expect after death—I'm actually scared. Do others feel this way?" Wants to explore religious beliefs—feels lack in his life. Said he would like to talk with hospital minister—will arrange for tomorrow.

E. Nolan, RN

ACTUAL OR POTENTIAL HEALTH PROBLEM

Spiritual Distress: Anxiety related to concerns about relationship with God as manifested by self-report

EXPECTED OUTCOME

Before discharge, the patient will:

- Identify his religious beliefs

NURSING INTERVENTIONS	RATIONALE	EVALUATIVE STATEMENT
Assist the patient to (1) identify the spiritual beliefs he had as a child and the origin of these beliefs, (2) evaluate these beliefs in terms of his life experiences, and (3) reaffirm, modify, or reject these beliefs or develop new spiritual beliefs.	Life experiences may challenge religious beliefs that were uncritically held as a child.	12/30/25 Outcome partially met. Patient states he has a much clearer concept of God and no longer fears that God will reject him for ignoring him for so long … but believes he also has a lot to learn. *E. Nolan, RN*

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Assist the patient to assess whether his newly articulated spiritual beliefs are life affirming or life denying and the degree to which they meet his needs for meaning and purpose, love and relatedness, and forgiveness.	Because spiritual beliefs can exert positive (life-affirming) and negative (life-denying) influences on a person's life, people should have some criteria to use when evaluating their beliefs.
Refer the patient to the hospital minister for assistance with the problem.	Patient may value speaking with a minister.

EXPECTED OUTCOME

Before discharge, the patient will:

- Reconcile his life up until the present with God

NURSING INTERVENTIONS	RATIONALE	EVALUATIVE STATEMENT
Reassure the patient that many people get involved in day-to-day living to the extent that they forget about God, and that in some religions, people believe that God uses illness and other stressors to invite people to rethink their spiritual beliefs. In these traditions, God is often pictured with open arms waiting to welcome a child home.	Images of a stern and unyielding God ready to strike down transgressors may contribute to a patient's spiritual distress. The need for forgiveness is a universal spiritual need.	12/30/25 Outcome met. "This minister has really helped. I wish I had talked to him a long time ago. I've carried so much guilt about my divorce and some other things—thought God would never forgive me. I feel so much more at peace now." *E. Nolan, RN*
Refer the patient to a spiritual advisor for help in experiencing forgiveness if he mentions guilt feelings.	Guilt often inhibits people from seeking and experiencing the forgiveness they desire.	
Communicate to the patient the importance of people accepting themselves—with all their strengths and weaknesses.	Many people have unrealistic self-expectations.	

EXPECTED OUTCOME

Before discharge, the patient will:

- Verbalize that his spiritual beliefs have become a source of strength and peace rather than anxiety

NURSING INTERVENTIONS	RATIONALE	EVALUATIVE STATEMENT
Encourage the patient to compare the role of spiritual beliefs in his life before, during, and after hospitalization.	This highlights the positive and negative roles spiritual beliefs can play. It may motivate the patient to continue searching if he values his present experience.	12/30/25 Outcome met. "It's good to be able to feel more peaceful about whatever the future brings. I'm anxious to get out of here because there's a lot I want to do with God's help." *E. Nolan, RN*

EXPECTED OUTCOME

Before discharge, the patient will:

- Increase night sleep to at least 6 undisturbed hours

NURSING INTERVENTIONS	RATIONALE	EVALUATIVE STATEMENT
Nurse on the night shift checks on the patient at the beginning of the	Nursing supervision of the patient at bedtime rules out other factors that	12/30/25 Outcome met. Patient slept last night from midnight to 0600.

shift to make sure he is comfortable and ready for sleep.	may interfere with sleep.	Will continue to monitor. *E. Nolan, RN*
Use power of suggestion to enhance sleep: *"I'm sure when I check back you'll be sound asleep."*	Suggestion has been shown to enhance the therapeutic effect of other interventions.	
If sleep remains disturbed, try relaxation exercises or guided imagery (see Chapter 35).	As spiritual anxiety decreases, sleep should improve. If sleep does not improve, other contributing factors and interventions will need to be explored.	

SAMPLE DOCUMENTATION

12/27/25, 1500, nursing

B. Hanks, Protestant minister, here to see patient at 1300. Afterward, patient said he felt "a whole lot better." Reported minister had assured him that many people in the hospital with a serious illness go through exactly what he is experiencing now—this thought seemed to decrease much of his anxiety. Minister had reinforced nurse's suggestion that he explore his religious beliefs and he has already jotted down some thoughts. "I knew you fixed bodies in hospitals but didn't know you fix souls, too." Patient looking forward to minister's visit tomorrow.

E. Nolan, RN

DEVELOPING CLINICAL REASONING AND CLINICAL JUDGMENT

. Assess your spiritual well-being. To what extent are you able to meet your needs for love and belonging, meaning and purpose, and forgiveness? If confronted with a life-threatening or chronic illness, would you be able to draw on religion or spirituality as a source of strength? Do you believe you need any special skills to develop to better meet the spiritual needs of your patients? Compare your responses to those of your classmates and explore reasons for differences.

. Poll your classmates and see if they agree strongly, agree, disagree, or disagree strongly with the following statements. Discuss reasons for the differences in your answers and how this is likely to affect your professional practice.

- Prayer has the power to heal physical, mental, and spiritual illness.
- Nurses who do not pray for their patients are deficient professional caregivers.
- Nurses who do not offer to pray with their patients are deficient professional caregivers.

. How would you respond to a patient who tells you that he isn't very religious but is now wondering if there is a God, and if so, wonders where he stands in relation to God now that his life is in jeopardy? Think about how your personal experience of religion or spirituality colors your response, and determine whether your personal experience of religion or spirituality has prepared you well to respond to these queries.

. You are a male nurse. The husband of your female patient requests that you get a female nurse to provide her care because their Muslim religion demands this. You are short-staffed and not sure you can accommodate this request. Do you make honoring his request a priority? Why or why not?

. When a nurse is caring for a scared, possibly mechanically ventilated, and dying patient with COVID-19 who is isolated from friends, family, personal clergy, and even hospital chaplains, should they ever initiate an offer of prayer? If so, under what circumstances might a nurse ethically do so? And practically, how could a nurse do this in a therapeutic manner? (Taylor, E. J., 2020).

. Your patient with advanced stage cancer is in danger of bleeding out and may require a life-saving blood transfusion. She is a practicing Jehovah's Witness. Do you inform the team that she cannot receive blood transfusions, even if these would be life-saving?

. Your 26-year-old patient on an inpatient mental health unit is 13 weeks' pregnant and undecided about continuing the pregnancy. You are working in a Catholic hospital and know that abortion is not an option on site. Do you explore more with the patient how committed she is to continuing the pregnancy, ready to offer abortion options if she chooses to terminate?

PRACTICING FOR NCLEX

. A hospice nurse is caring for a patient who is dying of pancreatic cancer. The patient tells the nurse, "I feel no connection to God" and "I'm worried that I've found no real meaning in life." What is the nurse's best response to this patient?

a. Give the patient a hug and tell them that their life still has meaning.

b. Arrange for a spiritual advisor to visit the patient.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

c. Ask if the patient would like to talk about their feelings.
d. Call in a close friend or relative to talk to the patient.

. A nurse who was raised as a strict Roman Catholic but is no longer practicing stated they could not assist patients with spiritual distress because they recognize only a "field of power" in each person. The nurse says to her colleague, "My parents and I hardly talk because I've deserted my faith. Sometimes I feel really isolated from them and God—if there is a God." These statements reveal which unmet spiritual need?

a. Meaning and purpose
b. Forgiveness
c. Love and relatedness
d. Strength for everyday living

. A nurse in a long-term care facility is performing spirituality assessments of residents on their unit. What is the best question the nurse could use to assess for spiritual needs?

a. "Can you describe your usual spiritual practices and how you maintain them daily?"
b. "Are your spiritual beliefs causing you any concern?"
c. "How can I and the other nurses help you maintain your spiritual practices?"
d. "How do your religious beliefs help you to feel at peace?"

. A patient who stated their religion as Jewish at the intake interview was served a kosher meal ordered from a restaurant on a paper plate because the hospital had no provision for kosher food or dishes. The patient became angry and accused the nurse of insulting him, emphatically stating, "I want to eat what everyone else does—and give me decent dishes." After analyzing the data, the nurse returns to the patient and makes which of these statements?

a. "I'm terribly sorry, I should have ordered kosher food and dishes as well."
b. "Did someone on the staff behave condescendingly or critically?"
c. "It seems difficult to please you today."
d. "We did not ask about your dietary preferences; tell me what you usually eat."

. A surgeon tells a patient who is a Jehovah's Witness that they need emergency surgery to repair an aortic aneurysm, which will require blood transfusions. The patient states, "If I receive blood, I will not go to paradise. It is against my religion." What nursing response to the patient is appropriate?

a. "I understand you will not receive blood products, even if it means you will die."
b. "Please listen to the surgeon; I've seen many aneurysms successfully repaired"
c. "Have you discussed your decision to refuse surgery with your family?"
d. "What can I say to help you through this difficult decision?"

. The Roman Catholic family of an infant born with hydrocephalus requests a baptism for their infant. The nurse advocates for the family's wishes to be honored for which reason?

a. Baptism frequently helps postpone or prevent death or suffering.
b. It is legally required that the nurse provide for this care when requested.
c. It is a nursing function to assure the salvation of the infant.
d. Not facilitating the baptism may increase the family's sorrow and suffering.

. A nurse is caring for patients in a long-term care facility. Which nursing actions are appropriate based on the religious beliefs of these patients? Select all that apply.

a. Asking a Buddhist if they have any diet restrictions related to the observance of holy days
b. Asking a Christian Scientist who is in traction if they would like to try nonpharmacologic pain measures
c. Administering medications to a Muslim patient and avoiding touching the patient's lips
d. Asking a Roman Catholic patient if they would like to attend Mass in the common room on Sunday
e. Avoiding scheduling treatment and procedures on Saturday for a Hindu patient
f. Consulting with the medicine man of a Native American patient and incorporating their suggestions into the care plan

. A nurse who is caring for patients on a pediatric unit is assessing children's spiritual needs. Which is the most important source of learning for a child's own spirituality?

a. Child's church or religious organization
b. What their parents say about God and religion
c. Their parents' behavior in relationship to the family, others, and to God
d. Family's spiritual advisor

. A nursing student is caring for a patient admitted with chest pain related to aortic valve stenosis. The student notes the patient, who had been calm and cooperative the day before, has become contemplative and withdrawn, stating, "I've never thought much about dying, but my chances of making it through tomorrow's surgery are 50-50." How does the

student best respond when the clinical professor asks the student why this behavior likely surfaced later in the patient's admission?

a. Patients usually want to maintain privacy about their spiritual needs.
b. People are better able to focus on spiritual needs after their spiritual advisor visits.
c. Family members and close friends often initiate spiritual concerns.
d. Illness increases spiritual concerns, which may initially be difficult to verbalize.

. A nurse who is comfortable with spirituality is caring for a patient who needs spiritual counseling. What action will the nurse take first?

a. Calling the patient's own spiritual advisor
b. Asking if the patient has a spiritual advisor they wish to consult
c. Counseling the patient and, if unsuccessful, making a referral to a spiritual advisor
d. Explaining the best health options for the patient to the spiritual advisor

. A patient states they feel very isolated from their family and church, and even from God, "in this huge medical center so far from home." When preparing expected outcomes for this patient, which most appropriately measures relief of the patient's spiritual distress?

a. The patient will express satisfaction with the compatibility of their spiritual beliefs and everyday living.
b. The patient will identify spiritual beliefs that meet their need for meaning and purpose.
c. The patient will express peaceful acceptance of limitations and failings.
d. The patient will identify spiritual supports available to them in this medical center.

. A patient who lost their home, spouse, and children in a fire is depressed and states that they have no reason to live. The patient states, "My family was my life." The nurse documents a health problem of Spiritual Distress based on the patient's inability to find meaning and purpose in their current situation. What is the priority nursing action for this patient?

a. Asking the patient which spiritual advisor they would like you to call
b. Recommending that the patient engage in spiritual or religious readings
c. Determining what has given the patient meaning and purpose in the past
d. Reminding the patient that God is a loving and personal God

. After terminating a pregnancy, a patient tells the nurse, "I shouldn't have had that abortion because I'm Catholic, but what else could I do? I'm afraid I'll never get close to my mother or back in the Church again." They then talk with their priest about this feeling of guilt. Which evaluation statement shows a solution to the problem?

a. Patient stated, "I wish I had talked with the priest sooner. I now know God has forgiven me, and my mother is beginning to understand."
b. Patient has slept from 10 PM to 6 AM for 3 consecutive nights without medication.
c. Patient has developed mutually caring relationships with others.
d. Patient has identified several spiritual beliefs that give purpose to their life.

. A parish nurse is speaking to a congregant whose adolescent child was arrested for shoplifting. The congregant is very angry, stating they cannot face the child, let alone discuss the situation: "I just will not tolerate a thief." What nursing action will best assist the congregant at this time?

a. Assuring the congregant that many parents feel the same way
b. Reassuring the congregant that many teenagers act rebelliously and that it will pass
c. Assisting the congregant to identify how withholding forgiveness hurts them
d. Asking the congregant if they have spent sufficient time with their child

. A hospice nurse who provides pastoral care is teaching nursing students about the three spiritual needs believed to be common to all people. Which of these will the nurse include in the discussion? Select all that apply.

a. Food, clothing, and shelter
b. Meaning and purpose
c. Family
d. Love and relatedness
e. Forgiveness
f. Rules to live by

ANSWERS WITH RATIONALES

. **c.** When caring for a patient who is in spiritual distress, the nurse should listen to the patient first, then ask whether the patient would like to visit with a spiritual advisor. Arranging for a spiritual advisor first may not be respectful of the patient's wishes. A hug and false reassurances do not address the problem of spiritual distress. Talking to friends or

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

relatives may be helpful, but only if the patient agrees.

. **c.** The data point to an unmet spiritual need to experience love and belonging, given the nurse's estrangement from their family and God after leaving the church. The other options may represent other needs this nurse has, but the nurse's statements do not support them.

. **c.** Questioning how the staff can meet patients' spiritual practices assesses spiritual needs. Asking the patient to describe spiritual practices is an assessment of spiritual practices. Asking about concerns assesses spiritual distress, and asking about feeling at peace assesses the need for forgiveness.

. **d.** On the basis of the patient's stated religion, the nurse assumed they would want a kosher diet. This is a form of stereotyping. When evaluating the outcome of the situation, the nurse returns to the first step of the nursing process and assesses the patient's dietary practices and preferences.

. **c.** Patients who practice the Jehovah's Witness faith believe blood transfusions violate God's laws and do not allow them. The nurse supports the patient's beliefs. It is disrespectful of the nurse to attempt to coerce a decision or impose their beliefs on the patient.

. **d.** Failure to ensure that an infant baptism is performed when parents desire it may greatly increase the family's sorrow and suffering. Whether baptism postpones or prevents death and suffering is a religious belief that is insufficient to bind all nurses. There is no legal requirement regarding baptism, and although some nurses may believe part of their role is to ensure the salvation of the infant, this function could be rejected by many.

. **a, b, d, f.** The nurse should ask a Buddhist if they have any diet restrictions related to the observance of holy days. Since Christian Scientists avoid the use of pain medications, the nurse should offer nonpharmacologic pain relief measures. A nurse administering medications to a Hindu patient avoids touching the patient's lips. A nurse should ask a Roman Catholic if they would like to attend Mass on Sunday. The nurse is careful not to schedule treatment and procedures on Saturday for a Jewish patient who observes the Sabbath. The nurse would appropriately consult with the medicine man of a Native American patient and incorporate their suggestions into the care plan.

. **c.** Children learn most about their own spirituality from how their parents behave in relationship to one another, their children, others, and God (or a higher being). What parents say about God and religion, the family's spiritual advisor, and the child's church or religious organization are less important sources of learning.

. **d.** Illness may increase spiritual concerns, which many patients find difficult to initially express. The other options presume patients are purposefully secretive or must speak with a spiritual advisor, friends, or family to promote discussion of spiritual concerns. Spirituality is anything that pertains to a person's relationship with a nonmaterial life force or higher power; there is no universal definition, as the experience is individual and personal.

. **b.** Even when a nurse feels comfortable discussing spiritual concerns, they should always determine whether the patient has a spiritual advisor they would like to consult. Calling the patient's spiritual advisor may be premature if it is a matter the nurse can handle. The other two options deny the patient's right to speak privately with their spiritual advisor from the outset, if that is their preference.

. **d.** Each of the four options represents appropriate spiritual goals, but identifying spiritual supports available to this patient in this medical center at this point in time, is the most appropriate and realistic.

. **c.** The nurse prioritizes determining what, in addition to their family, has given the patient's life meaning and purpose in the past. This helps the patient focus on their strengths. This assessment data can be used to further plan individualized spiritual care.

. **a.** The patient's statements indicate feelings of guilt, which has caused spiritual distress. Only option a clearly evaluates whether the patient's feelings of guilt have resolved after speaking to the priest.

. **c.** Helping the congregant identify how their unforgiving feelings may be harmful to themselves is the only intervention that directly addresses forgiveness, a universal spiritual need. Assuring the congregant that many parents would feel the same way or that many teenagers shoplift out of rebelliousness may make them feel better initially, but this does not address the benefits of forgiveness. Suggesting the congregant may not have spent enough time with their child may be untrue and could promote guilty feelings, when they may be unwarranted.

. **b, d, e.** Meaning and purpose, love and relatedness, and forgiveness are the three spiritual needs believed to be common to all people. Option a is a human need as described by Maslow, as is family (love and belonging). Many people live by a set of rules, but this is not a common spiritual need.

Glossary

A

AAPIE assessing, analysing, planning, implementing, and evaluating.

Abduction lateral movement of the body part away from the midline of the body

Abscess collection of infected fluid that has not drained

Absorption process by which drugs are transferred from the site of entry into the body to the bloodstream

Abstinence refraining from having sex

Accommodation (1) ability to adjust the eye to see at various distances; (2) process by which intellectual acts are changed to handle increasingly complex information

Accountable care organization (ACO) group of health care entities (e.g., hospitals, primary care settings, and specialty care practices) organized via incentives to deliver the most efficient and high-quality care for the population served

Accreditation process by which an educational program is evaluated and then recognized as having met certain predetermined standards of education

Acid substance containing a hydrogen ion that can be liberated or released

Acidosis condition characterized by a proportionate excess of hydrogen ions in the extracellular fluid, in which the pH falls below 7.35

Acquired immunodeficiency syndrome (AIDS) condition in which the body's immune system is rendered ineffective as a result of infection by the retrovirus HIV

Active euthanasia someone other than the patient commits an action with the intent to end the patient's life, for example, injecting the patient with a lethal dose of a drug

Active exercise joint movement activated by the person

Active immunity antibodies against harmful effects of microorganisms or toxins that are self-produced

Active transport movement of ions or molecules across cell membranes, usually against a pressure gradient and with the expenditure of metabolic energy

Activities of daily living self-care activities such as eating, bathing, dressing, and toileting

Actual loss loss that can be recognized by others as well as by the person sustaining the loss, such as loss of a limb or a spouse

Actual nursing diagnoses problems validated by the presence of major defining characteristics and possessing four components: label, definition, defining characteristics, and related factor

Actual problems health problems that have been validated by the presence of major defining characteristics

Acupuncture procedure consisting of placing very thin, short, sterile needles at particular acupoints, believed to be centers of nerve and vascular tissue, along a meridian to either increase or decrease the flow of chi along the meridian, restoring the balance of yin and yang, and thereby contributing to healing

Acute illness rapidly occurring illness that runs its course, allowing a person to return to one's previous level of functioning

Acute pain episode of pain that lasts from seconds to less than 6 months

Adaptation adjustment of living with other living things and environmental conditions

Addiction a pattern of compulsive use of addictive substances for means other than those prescribed

Addictive substance to which a person develops a psychological and physiologic dependency

Adduction movement of a body part toward the midline of the body

Adjuvant drugs typically used for other purposes, but also used to enhance the effect of opioids by providing additional pain relief

Adolescence the period of time between childhood and adulthood; a time of rapid physical change, reproductive maturity, and emotional development

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

ADPIE assessing, diagnosing, planning, implementing, and evaluating

Advance care planning process of planning for future care in the event a person becomes unable to make their own decisions

Advance directive written directive that allows people to state in advance what their choices for health care would be if certain circumstances should develop

Advanced practice registered nurse (APRN) registered nurse educated at the master's or post-master's level in a specific role and for a specific population; examples include nurse practitioners, clinical nurse specialists, nurse anesthetists, and nurse midwives

Adventitious breath sounds abnormal breath sound heard over the lungs

Adverse drug reactions undesirable effects other than the intended therapeutic effect of a drug

Adverse reaction an adverse reaction is an unwanted or harmful reaction experienced following the administration of a drug, diagnostic test, or therapeutic intervention under normal conditions of use.

Advocacy protection and support of another's rights

Aerobic bacteria bacteria that require oxygen to live and grow

Aerobic exercise exercise that promotes cardiovascular fitness; it increases blood flow, heart rate, and the metabolic demand for oxygen over a period of time

Aerobic requiring oxygen to live and grow

Afebrile a condition in which the body temperature is not elevated

Affective learning changes in attitudes, values, and feelings

Ageism attitudes that stereotype the older adult on the basis of chronologic age

Agency for Healthcare Research and Quality (AHRQ) a group of multidisciplinary experts who use research as well as a broad range of input from professional and consumer organizations and individuals to develop clinical practice guidelines

Agglutinin an antibody that causes a clumping of specific antigens

Aggressive behavior standing up for one's rights in a negative manner that violates the rights of others

Agnostic person who believes that nothing can be known about the existence of a god

Airborne transmission spreading of microorganisms that are less than 5 mcm when an infected host coughs, sneezes, or talks, or when the organism becomes attached to dust particles

Albuminuria albumin in the urine; an indication of kidney disease

Alkali substance that can accept or trap a hydrogen ion; synonym for base

Alkalosis condition, characterized by a proportionate lack of hydrogen ions in the extracellular fluid concentration, in which the pH exceeds 7.45

Allergic effect immune system response that occurs when the body interprets an administered drug as a foreign substance and forms antibodies against the drug

Allodynia characteristic feature of neuropathic pain that occurs after a normally weak or nonpainful stimuli, such as a light touch or a cold drink

Allopathy the term generally used to describe "traditional" medical care (biomedicine), dominant for about 100 years, which spearheaded remarkable advances in biotechnology,
surgical interventions, pharmaceutical approaches, and diagnostic tools

Allostasis the process of achieving stability or homeostasis through physiologic or behavioral change

Allow natural death (AND) order an order that no attempts are to be made to resuscitate a patient who stops breathing or whose heart stops beating

Alopecia hair loss or baldness

Alternative care general term used to identify various methods of nonhospital health care, including residential housing, daycare, respite care, hospice, and extended-care facilities

Alternative modalities methods not included in the scope of conventional medical care

Alveoli small air sacs at the end of the terminal bronchioles that are the site of gas exchange

Alzheimer disease type of dementia in which discrete patches of brain tissue degenerate; this devastating disease eventually affects all body functions

Ambulatory care health care settings located in areas that are convenient for people to walk into and receive care; may be provided in hospitals, clinics, or centers

Amino acid basic building blocks used to manufacture protein and the end products of protein digestion

Ampule glass flask containing a single dose of medication for parenteral administration

Anaerobic bacteria bacteria that can live without oxygen

Anaerobic capable of living without oxygen

Anaerobic exercise exercise in which the supply of oxygen is less than the demand created by contracting muscles; oxygen debt results

Analgesic drug pharmaceutical agent used to relieve pain

Analytics discovery, interpretation, and communication of meaningful patterns in data

Anaphylactic reaction/Anaphylaxis severe reaction occurring immediately after exposure to a drug; characterized by respiratory distress and vascular collapse

Andragogy the study of teaching adults

Anesthetic agent that produces states such as loss of consciousness, analgesia, relaxation, and loss of reflexes

Angina a temporary imbalance between the amount of oxygen needed by the heart and the amount delivered to the heart muscles

Anion ion that carries a negative electric charge

Ankylosis fixation or immobilization of a joint

Anorexia lack or loss of appetite for food

Anorexia nervosa eating disorder characterized by the denial of appetite and bizarre eating habits

Anoxia absence of oxygen

Antagonistic effect combined effect of two or more drugs that produces less than the effect of each drug alone

Anthropometric measurements of the body and body parts

Antibacterial agent that kills bacteria or suppresses their growth

Antibody immunoglobin produced by the body in response to a specific antigen

Anticipatory loss condition in which a person displays loss and grief behaviors for a loss that has yet to take place

Antigen foreign material capable of inducing a specific immune response

Antimicrobial antibacterial agent that kills bacteria or suppresses their growth

Antipyretic agent that reduces fever

Antiracism requires everyone to engage in a daily practice of actively combating racial structures, institutions, and practices

Antiseptic substance that inhibits the growth of bacteria

Anuria technically, no urine voided; 24-hour urine output is less than 100 mL

Anus opening at the end of anal canal

Anxiety vague sense of impending doom or apprehension precipitated by new and unknown experiences

Apnea absence of breathing

Applied research (practical research) research designed to directly influence or improve clinical practice

Aromatherapy the use of essential oils of plants to treat symptoms

Arousal condition in which the cortical area of the brain receives and responds appropriately to stimuli

Arterial blood gas a diagnostic test examining arterial blood; used to determine the pressure exerted by oxygen and carbon dioxide in the blood

Ascites accumulation of fluid in the peritoneal cavity

Asepsis absence of disease-producing microorganisms; using methods to prevent infection

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Asphyxiation stoppage of breathing or the lack of air reaching the lungs; synonym for suffocation

Aspiration misdirection of oropharyngeal secretions or gastric contents into the larynx and lower respiratory tract

Assault threat or an attempt to make bodily contact with another person without that person's permission

Assertive behavior ability to stand up for oneself and others using open, honest, and direct communication

Assess to systematically and continuously collect, validate, and communicate patient data

Assimilation process by which a person interprets information to fit the current level of cognition

Assisted suicide the act of making a means of suicide (e.g., providing pills or a weapon) available to a patient with knowledge of the patient's intention; in assisted suicide, someone makes the means of death available but does not act as the direct agent of death

Atelectasis incomplete expansion or collapse of a part of the lungs

Atheist person who denies the existence of a god

Atria upper chambers of the heart

Atrioventricular (AV) node a node of specialized heart muscle located in the septal wall of the right atrium; receives impulses from the sinoatrial node and transmits them to the atrioventricular bundle

Atrioventricular bundle a bundle of modified heart muscle that transmits the cardiac impulse from the atrioventricular node to the ventricles, causing them to contract

Atrophy decrease in the size of a body structure

Attachment active, affectionate, reciprocal relationship between two persons

Attitude feeling or emotion, generally including a positive or negative judgment toward people, objects, or ideas

Auditory pertaining to hearing

Aura consists of at least seven layers of energy that surround the body and relate to the chakras

Auscultation listening for sounds within the body

Auscultatory gap period of diminished or absent Korotkoff sounds; it occurs during the manual measurement of blood pressure in the latter part of phase I and during phase II

Authoritative knowledge knowledge that comes from an expert and is accepted as truth based on a perceived level of expertise

Autocratic leadership leadership style in which the leader assumes complete control over the decisions and activities of the group

Autologous transfusion occurs when a patient donates one's own blood for a transfusion

Autonomic bladder bladder no longer controlled by the brain because of injury or disease; void by reflex only

Autonomy self-determination; being independent and self-governing

Ayurveda a science of life that delineates the diet, medicines, and behaviors that are beneficial or harmful for life and considers that balance among people, the environment, and the larger cosmos is integral to human health

B

Bacteria the most significant and most commonly observed infection-causing agents

Bacteriuria condition that occurs when bacteria enter the bladder during catheterization, or when organisms migrate up the catheter lumen or the urethra into the bladder; bacteria in the urine

Bandage piece of gauze or other material used to cover a wound

Basal metabolism amount of energy required to carry out involuntary activities of the body at rest

Base of support foundation that provides stability for an object

Base substance that can accept or trap a hydrogen ion; synonym for alkali

Basic human needs something essential to the health and survival of humans; common to all people

Basic research (pure research) research designed to generate and refine theory; the findings are often not directly useful in practice

Battery assault that is carried out

Bedside report standardized, streamlined shift report system at the bedside; helps ensure the safe handoff of care between nurses by involving the patient and family

Beliefs special class of intellectual attitudes based primarily on faith as opposed to fact

Beneficence principle of doing good

Bereavement care continuation of care, usually up to 1 year, for the family after loss of a loved one

Bereavement state of grieving or going through the grief process

Big data accumulation of data from various sources, combined with new technologies that allow for the transformation of data to information

Bilateral pertaining to two sides of the body

Binder type of bandage, usually designed to fit a large body area

Bioethics ethics that encompass all those perspectives that seek to understand human nature and behavior, the domain of social science, and the natural world

Biofilm a thick grouping of microorganisms

Biologic sex term used to denote chromosomal sexual development—male (XY) or female (XX)

Biopsy removal of a piece of tissue for microscopic examination

Bioterrorism the deliberate spread of pathogenic organisms into a community to cause widespread illness, fear, and panic

Bisexuality having sexual feelings for people of both sexes

Blended competencies the set of intellectual, interpersonal, technical, and ethical/legal capacities needed to practice professional nursing

Blended family two single-parent families joined together to form a new family unit

Blockchain digital information (the "block") stored in a public database (the "chain"). Blockchain can significantly increase data security within health care and the nursing profession due to its superior data accessibility, privacy, auditability, and efficiency.

Blood pressure force of blood against arterial walls

Blood typing the laboratory examination to determine a person's blood type

Body image how a person experiences one's body

Body language nonverbal communication

Body mass index (BMI) ratio of height to weight

Body mechanics efficient use of the body as a machine and as a means of locomotion

Body substance isolation (BSI) type of isolation that considers all body substances as potentially infective regardless of a person's diagnosis

Bolus single injection of a concentrated solution administered intravenously

Bonding process of initial emotional fusing of the mother and infant that occurs most often in the first few hours after birth and is necessary for later attachment

Bowel incontinence the inability of the anal sphincter to control the discharge of fecal and gaseous material

Bowel movement emptying of the intestinal tract; synonym for defecation

Bowel training program program that manipulates factors within a person's control (timing of defecation, exercise, diet) to produce a regular pattern of comfortable defecation without medication or enemas

Bradycardia slow heart rate

Bradypnea slow rate of breathing

Breakthrough pain temporary flare-up of moderate to severe pain that occurs even when the patient is taking around-the-clock medication for persistent pain

Bronchial breath sounds those heard over the larynx and trachea are high-pitched, harsh "blowing" sounds, with sound on expiration being longer than inspiration

Bronchodilator medication that relaxes contractions of smooth muscles of the bronchioles

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Bronchoscopy visual examination of the trachea and bronchi

Bronchovesicular breath sounds normal breath sounds heard over the mainstem bronchus; they are moderate blowing sounds, with inspiration equal to expiration

Bruit unusual sound, usually abnormal, heard in auscultation

Buffer substance that prevents body fluid from becoming overly acid or alkaline

Bulimia eating disorder characterized by episodes of gorging followed by purging; often occurs in conjunction with anorexia nervosa

Bullying negative, often repetitive, disruptive behavior; also referred to as horizontal violence, lateral violence, and professional incivility

Bundles evidence-based best practices that have proven positive outcomes when implemented together to prevent infection

Burnout (1) cumulative state of frustration with the work environment that develops over a long time; (2) behaviors exhibited as the result of prolonged occupational stress

C

Calorie measure of heat, or energy; kilocalorie, commonly referred to as a calorie, defined as the amount of heat required to raise 1 kg of water 1°C

Capillary filtration passage of fluid across the wall of the capillary; results from the force of blood "pushing" against the walls of the capillaries

Capitation fixed amount per patient for a specified time period paid to a health care service provider for the delivery of health care services

Capnography a method to monitor ventilation and, indirectly, blood flow through the lungs

Carbohydrate organic compounds (commonly known as sugars and starches) that are composed of carbon, hydrogen, and oxygen; the most abundant and least expensive source of calories in the diet worldwide

Cardiac output volume of blood pumped from the left ventricle per minute

Cardinal signs body temperature, pulse and respiratory rates, and blood pressure; synonym for vital signs

Cardiopulmonary relating to the heart and the lungs

Cardiovascular relating to the heart and blood vessels

Care bundle a structured way of improving processes of care and patient outcomes: A small straightforward set of evidence-based practices—generally three to five—that when performed collectively and reliably, have been proven to improve patient outcomes.

Care coordination deliberate organization of patient care activities between two or more participants (including the patient) to facilitate the appropriate delivery of quality health care services in an efficient person-centered manner; mechanism to make sure that patients get the right care at the right time in the most efficient and cost-effective manner, by the right person in the right setting

Care coordinator care provider (nurse case manager, social worker, community health worker, or lay person) who is responsible for identifying a person's health goals and coordinating services and providers to meet those goals

Care transition continuous process in which a patient's care shifts from being provided in one setting of care to another

Care-based approach approach to bioethics that directs attention to the specific situations of individual patients viewed within the context of their life narrative

Caregiver burden stress responses experienced during prolonged periods of home care by family caregivers

Caries cavities of the teeth

Caring moral imperative that guides nursing praxis (education, practice, and research); action and competencies that aim toward the good and welfare of others

Cartilage hard, nonvascular connective tissue found in the joints as well as in the nose, ear, thorax, trachea, and larynx

Cascade iatrogenesis downward spiral or sequence of adverse events often triggered by a medical or surgical intervention during the hospitalization of an older adult

Case management the process of coordinating an individual's health care for the purpose of maximizing positive outcomes and containing costs

Cathartic medication that strongly increases gastrointestinal motility and promotes defecation

Catheter tube for injecting or removing fluids

Cation ion that carries a positive electric charge

Center of gravity point at which the mass of an object is centered

Centers for Disease Control and Prevention (CDC) U.S. government facility whose responsibilities include investigation, identification, prevention, and control of disease

Central venous catheter venous access device usually introduced into the subclavian or internal jugular veins and passed to the superior vena cava just above the right atrium

Certification process by which a person who has met certain criteria established by a nongovernmental association is granted recognition

Cerumen wax in the external ear canals, consisting of a heavy oil and brown pigment

Ceruminal gland gland found in the external auditory canal that secretes cerumen

Chakra concentrated areas of energy aligned vertically in the body, which relate to each other as well as to specific areas of the body/mind/spirit

Change agent person who purposefully and systematically implements change

Change process of transforming, altering, or modifying something

Change-of-shift report communication method used by nurses who are completing care for a patient to transmit patient information to nurses who are about to assume responsibility for continuing care; may be exchanged verbally in a meeting or audiotaped

Channel term used in communication theory to denote the medium selected to convey the message; the channel may target any of the receiver's senses

Chart computerized or paper medical record containing information such as medical orders, assessments, and care; nursing documentation of plan of care, assessments, and interventions; and diagnostic/surgery results

Charting by exception shorthand method for documenting patient data that are based on well-defined standards of practice; only exceptions to these standards are documented in narrative notes

Cheilosis ulceration of the lips

Chemical emergency event caused by the release of a chemical compound that has the potential for harming people's health

Chemical name precise description of a drug's chemical composition

Cheyne–Stokes respirations gradual increase and then gradual decrease in depth of respirations followed by a period of apnea

Child maltreatment an act or series of acts of commission (abuse) or omission (neglect) by a parent or other caregiver that results in harm, potential for harm, or threat of harm to a child

Chiropractic health care profession that focuses on the relationship between the body's structure—mainly the spine—and its functioning; its practitioners primarily perform adjustments (manipulations) to the spine or other parts of the body with the goal of correcting alignment problems, alleviating pain, improving function, and supporting the body's natural ability to heal itself

Cholesterol fat-like substance found only in animal tissues; it is important for cell membrane structure, a precursor of steroid hormones, and a constituent of bile; high serum cholesterol levels are a risk factor in the development of atherosclerosis

Chronic illness irreversible illness that causes permanent physical impairment and requires long-term health care

Chronic pain episode of pain that lasts for 6 months or longer; may be intermittent or continuous

Chyme semifluid state that food is in when it leaves the stomach

Cilia microscopic, hair-like projections that propel mucus toward the upper airway so that it can be expectorated

Circadian rhythm rhythm that completes a full cycle every 24 hours; synonym for diurnal rhythm

Circumduction moving the distal part of the limb to trace a complete circle while the proximal end remains fixed

Cisgender gender identity or role performance that matches society's expectations based on biologic sex

Civil law rule that regulates relationships among people; synonym for private law

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Clear liquid diet diet that contains only foods that are clear liquids at room or body temperature—gelatin, fat-free broth, bouillon, ice pops, clear juices, carbonated beverages, and regular and decaffeinated coffee and tea

Cliché a stereotyped, trite, or pat answer

Climate change/crisis rising temperatures are fueling environmental degradation, natural disasters, weather extremes, food and water insecurity, economic disruption, conflict, and terrorism. Sea levels are rising, the Artic is melting, coral reefs are dying, oceans are acidifying, and forests are burning

Clinical ethics branch of bioethics concerned with ethical problems that arise within the context of caring for patients

Clinical information system computer-based system designed for collecting, storing, manipulating, and making available clinical information important to the health care delivery process

Clinical inquiry ongoing process of questioning and evaluating practice and advancing informed practice

Clinical judgment—from NCSBN (2019a): the result
or observed outcome of critical thinking and decision making

Clinical judgment refers to the result (outcome) of critical thinking or clinical reasoning; the conclusion, decision, or opinion a nurse makes

Clinical pathway/critical path/CareMap case management tools used to communicate the standardized, interdisciplinary plan of care for a particular group of patients; care guidelines and outcomes are specified for each day of the patient's stay

Clinical reasoning—from AACN (2021): "thought processes that allow health care providers to arrive at a conclusion"

Clinical reasoning a specific term usually referring to ways of thinking about patient care issues (determining, preventing, and managing patient problems); for reasoning about other clinical issues (e.g., teamwork, collaboration, and streamlining work flow); nurses usually use critical thinking

clinician burnout workplace syndrome resulting from chronic job stress that is a major problem across the nation

Clubbing rounding and swelling of nailbeds

Code of ethics principles that reflect the primary goals, values, and obligations of the profession

Cognition cerebral functioning; process of perceiving and understanding one's world

Cognitive development learning that occurs as a result of the internal organization of an event, which forms a mental schema (plan) and serves as a base for further schemata as one grows and develops (Piaget's theory of cognitive development)

Cognitive learning storing and recalling of new knowledge in the brain

Cognitive load term used to reference the amount of information a person can hold in their memory at one time

Cognitively skilled capable of thinking about the nature of things sufficiently to "make sense" of the world and to grasp conceptually what is necessary to achieve valued goals

Coitus sexual activity in which the penis is placed in the vagina; synonym for sexual intercourse

Colic acute abdominal pain caused by spasmodic contractions of the intestine during the first 3 months of life

Collaborative interventions interdependent nursing actions performed jointly by nurses and other members of the health care team

Collaborative practice what happens when multiple health workers from different professional backgrounds work together with patients, families, carers, and communities to deliver the highest quality of care

Collaborative problem actual or potential health problem that may occur from complications of disease, diagnostic studies, or the treatment regimen; the nurse works together with other members of the health care team toward its - resolution

Colloid osmotic pressure pressure exerted by plasma proteins on permeable membranes in the body; synonym for oncotic pressure

Colon section of the large intestine from the cecum to the rectum

Colonization presence of an organism residing in an individual's body but with no clinical signs of infection

Colostomy an opening into the colon that permits feces to exit through the stoma

Comfort-measures-only order an order written to indicate that the goal of treatment is a comfortable, dignified death and that further life-sustaining measures are no longer indicated

Common law law resulting from court decisions that is then followed when other cases involving similar circumstances and facts arise; common law is as binding as civil law

Communication process of sharing information; process of generating and transmitting meanings

Community health center regionalized service for vulnerable geographic populations with an emphasis on primary care and education, established to ensure that everyone who needs care has access regardless of ability to pay

Community specific population or group of people living in the same geographic area under similar regulations and having common values, interests, and needs

Community-based health care health care that is provided to people who live within a defined geographic region or who have common needs; designed to meet the needs of people as they move between and among health care settings

Compassion fatigue loss of satisfaction from providing good patient care

Competency—from ANA (2021): "an expected level of performance that integrates knowledge, skills, abilities, and judgment"

Complaint legal statement of the plaintiff's claim; once filed, it initiates legal proceedings

Complementary health approaches interventions that can be used with conventional medical interventions

Compliance act of completing what is expected of one

Comprehensive health assessment broad health assessment that includes a complete health history and physical assessment; it is usually conducted when a patient first enters a health care setting, with information providing a baseline for comparing later assessments

Computer-based record computer-generated patient data collection system that can be distributed among many caregivers in a standardized format, allowing them to compare and uniformly evaluate patient progress easily, or compare the progress of groups of patients with similar diagnoses

Computerized nursing care plans plans of patient care developed by computer software programs that enable the nurse to call up screens listing causes, goals, and related nursing interventions for nursing diagnoses and medical diagnoses

computerized provider order entry (CPOE) this section of the EHR is for the orders written by the health care provider that are deemed necessary for the patient such as required lab tests, procedures, medications, and treatments. This section was formerly known as the section of the paper medical record known as "physician orders"

Concept abstract images (ideas) that are formed as impressions from the environment and organized into symbols of reality

Concept mapping instructional strategy that requires learners to identify, graphically display, and link key concepts

Conceptual framework/model set of concepts, along with the statements that arrange the concepts into an understandable pattern

Concurrent audit evaluation of nursing care and patient outcomes conducted while the patient is receiving care; may use direct observation of nursing care, patient interview, and chart review

Concurrent evaluation the evaluation of nursing care and patient outcomes while the patient is receiving care, conducted by using direct observation of nursing care, patient interviews, and chart review to determine whether the specified evaluative criteria are met

Condom catheter tube for draining urine; applied externally to the penis and connected to a collection bag

Confer to consult with someone to exchange ideas or to seek information, advice, or instructions

Confidentiality respecting privileged information

Conflict engagement method by which nurses can comfortably and respectfully address conflict in the workplace (rather than avoiding conflict) by creating connections with others to build trust

Conflict management process used to work through conflicts in a way that minimizes negative effects and promotes positive consequences

Congestion presence of excessive fluids or secretions in an organ or body tissue

Conscientious objection refusal to participate in certain types of treatment and care based on the fact that these activities violate the nurse's personal and professional ethical beliefs and standards

Conscious sedation/analgesia analgesia used for short-term procedures in which the patient maintains cardiorespiratory function and can respond to verbal commands while the IV administration of sedatives and analgesics raises the pain threshold and produces an altered mood and some degree of amnesia

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Constipation passage of dry, hard fecal material

Consultation process in which two or more individuals with varying degrees of experience and expertise deliberate about a problem and its solution

Consumer the person who uses health care services (the patient)

Continent having self-control over urination

Continent urinary diversion surgical alternative that uses a section of the intestine to create an internal reservoir that holds urine, with the creation of a catheterizable stoma

Continuity of care coordination of services provided to patients before they enter a health care setting, during the time they are in the setting, and after they leave the setting

Continuum graduated scale

Contraception prevention of conception or pregnancy; also used to describe methods used for birth control

Contractual agreement pact made between two persons or parties for the achievement of mutually set goals

Contracture permanently contracted state of a muscle

Convalescent period stage of an illness that represents recovery from the illness (or surgery)

Coping mechanism patterns of behavior used to neutralize, deny, or counteract anxiety

Counseling giving guidance, assisting with problem solving

Crackles fine, crackling sounds made as air moves through wet secretions in the lungs

Creative thinking a process involving imagination, intuition, and spontaneity—factors that underpin the art of nursing

Credentialing general term that refers to ways in which professional competence is maintained

Crime offense against people or property; the act is considered to be against the government, referred to in a lawsuit as "the people," and the accused is prosecuted by the state

Crisis (1) point at which body temperature drops rapidly to normal; (2) occurs when coping and defense mechanisms are no longer effective, resulting in high levels of anxiety, disorganized behavior, and the inability to function normally

Crisis intervention five-step problem-solving technique to promote adaptation and improve future coping

Criteria specified behavior; for example, the measurable criteria in a patient goal specifies how the patient must perform the desired behavior

Critical thinking—from Scriven and Paul (1987): "Critical thinking is the intellectually disciplined process of actively and skillfully conceptualizing, applying, analyzing, synthesizing, and/or evaluating information gathered from, or generated by, observation, experience, reflection, reasoning, or communication, as a guide to belief and action"

Critical thinking indicators (CTIs) evidence-based descriptions of behaviors that demonstrate the knowledge, characteristics, and skills that promote critical thinking in clinical practice

Critical thinking thought that is disciplined, comprehensive, based on intellectual standards, and, as a result, well-reasoned; a systematic way to form and shape one's thinking that functions purposefully and exactingly

Critical/collaborative pathway case management plan that is a detailed, standardized plan of care developed for a patient population with a designated diagnosis or procedure; it includes expected outcomes, a list of interventions to be performed, and the sequence and timing of those interventions

Cross-matching act of determining the compatibility of two blood specimens

Cue significant information that is helpful in making decisions

Cultural assimilation process that occurs when a minority group, living as part of a dominant group within a culture, loses the cultural characteristics that made it different

Cultural blindness the process of ignoring differences in people and proceeding as though the differences do not exist

Cultural care deprivation a lack of culturally assistive, supportive, or facilitative acts in the health care setting

Cultural diversity (1) coexistence of different ethnic, biologic sex, racial, and socioeconomic groups within one social unit; (2) diverse groups in society, with varying racial classifications and national origins, religious affiliations, languages, physical size, biologic sex, sexual orientation, age, disability, socioeconomic status, occupational status, and geographic location cultural humility is the recognition of diversity and power imbalances among individuals, groups or communities, with the action of being open, self-aware, egoless, flexible, exuding respect and supportive interactions, focusing on both self and other to formulate a tailored response. Cultural humility is a process of critical self-reflection

and lifelong learning, resulting in mutually positive outcomes.

Cultural imposition tendency of some to impose their beliefs, practices, and values on another culture because they believe that their ideas are superior to those of another person or group

Cultural respect enables nurses to deliver services that are respectful of and responsive to the health beliefs, practices, and cultural and linguistic needs of diverse patients; critical to reducing health disparities and improving access to high-quality health care

Culturally competent care care delivered with an awareness of the aspects of the patient's culture

Culture conflict situation that occurs when people become aware of cultural differences, feel threatened, and respond by ridiculing the beliefs and traditions of others to make themselves feel more secure about their own values

Culture of safety organizational environment where "core values and behaviors resulting from a collective and sustained commitment by organizational leadership, management, and workers emphasize safety over competing goals"

Culture shock those feelings, usually negative, a person experiences when placed in a different culture

Culture sum total of human behavior or social characteristics particular to a specific group and passed from generation to generation or from one to another within the group

Cumulative effect condition that occurs when the body cannot metabolize a drug before additional doses are administered

CUS communication tool to assist in effective communication related to patient safety concerns; the acronym CUS stands for I'm Concerned, I'm Uncomfortable, This is unSafe (or This is a Safety issue)

Cutaneous pain superficial pain usually involving the skin or subcutaneous tissue

Cutaneous ureterostomy a type of incontinent cutaneous urinary diversion in which the ureters are directed through the abdominal wall and attached to an opening in the skin

Cyanosis bluish coloring of the skin and mucous membranes

Cyber terror the use of high-tech means to disable or delete critical electronic infrastructure data or information

Cystoscopy direct visual examination of the bladder, ureteral orifices, and urethra with a cystoscope

Cytologic study study of body cells and fluids

D

Dangling position in which the person sits on the edge of the bed with legs and feet dangling over the side of the bed

Data cluster grouping of patient data or cues that points to the existence of a patient health problem

Data information

Data visualization presentation of data in a pictorial or graphical format

Database all the pertinent patient information that enables a comprehensive and effective plan of care to be designed and implemented

Daycare center centers that provide care for infants, children, older people, and people with special health care needs

Death (1) irreversible cessation of all functions of circulatory and respiratory functions; (2) irreversible cessation of all functions of the entire brain, including the brainstem;
(3) termination of life

Debridement cleaning away devitalized tissue and foreign matter from a wound

Decentralized decision-making process autonomous, accountable professional nursing practice; a characteristic of a democratic leadership style and the heart of a self-governance model of unit organization

Decision making purposeful, goal-directed effort applied in a systematic way to make a choice among alternatives

Deductive reasoning cognitive process in which one examines a general idea and then considers specific actions or ideas

Deep vein thrombosis (DVT) formation of a blood clot ("thrombus") in a deep vein

Defamation of character an intentional tort in which one party makes derogatory remarks about another that diminishes the other party's reputation; slander is oral defamation of character; libel is written defamation of character

Defecation emptying of the intestinal tract; synonym for bowel movement

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Defendant the one being accused of a crime or tort

Defense mechanisms forms of self-deception; unconscious process the self uses to protect itself from anxiety or threats to self-esteem

Dehiscence separation of the layers of a surgical wound; may be partial, superficial, or a complete disruption of the surgical wound

Dehydration decreased water volume in body tissue

Delegation the transfer of responsibility for the performance of an activity to another individual while retaining accountability for the outcome delete personal health record (PHR)

Delirium a temporary state of confusion

Dementia organic impairment of intellectual functioning, gradually leading to interference with social or occupational functioning, memory, and often personality integration

Democratic leadership leadership style characterized by a sense of equality between the leader and followers

Deontologic ethical system in which actions are right or wrong independent of the consequences they produce

Dependent action nursing action carried out at the instruction or order of an authorized health care professional other than a nurse; synonym for physician-initiated or physician-prescribed intervention

Depersonalization subjective experience of the partial or total disruption of one's ego and the disintegration and disorganization of one's self-concept

Dermis layer of the skin below the epidermis

Desiccation dehydration; the process of being rendered free from moisture

Development increase in the complexity of function and progression to skill advancement

Development theory theory to describe the orderly and predictable process of the growth and development of humans, individualized by social, biologic, and environmental factors

Developmental crisis predictable patterns of behavior and change occurring throughout the lifespan

Developmental delay measure of development that lags behind the normal range for a given age

Developmental task successful achievement of psychomotor, psychosocial, or cognitive skills at certain periods in life; failure to obtain the developmental task can lead to unhappiness and difficulty with later tasks

Diagnosis (nursing) analysis of patient data to identify patient strengths and health problems that independent nursing intervention can prevent or resolve

Diagnosis-related groups (DRGs) classification of patients by major medical diagnosis for the purpose of standardizing health care costs

Diagnostic error failure to detect an actual unhealthy behavior or condition

Diaphoresis an excessive amount of perspiration, such as when the entire skin is moist

Diarrhea passage of liquid and unformed stools

Diastolic pressure least amount of pressure exerted on arterial walls, which occurs when the heart is at rest between ventricular contractions

Dietary Guidelines recommendations for choosing a healthy diet made by the U.S. Department of Agriculture and the U.S. Department of Health and Human Services

Diffuse pain pain that covers a large area

Diffusion tendency of solutes to move freely throughout a solvent from an area of higher concentration to an area of lower concentration until equilibrium is established

Digestion gastrointestinal system's breakdown process of food into particles small enough to pass into the cells and be used by the cells

Direct care intervention treatment performed through interaction with the patient

Direct contact way for organisms to enter the body that involves proximity between the susceptible host and an infected person or a carrier, such as through touching, kissing, or sexual intercourse

Direct transfusion infusion of blood while it is being taken from the donor

Disaster an emergency event of greater magnitude that requires the response of people outside the involved community

Discharge planning systematic process of preparing the patient to leave the health care facility and for maintaining continuity of care

Discharge summary description of where the patient stands in relation to problems identified in the record at discharge; documents any special teaching or counseling the patient received, including referrals

Discipline specific and unique body of knowledge that uses existing and new knowledge to creatively solve problems and meet human needs within ever-changing boundaries

Disease pathologic change in the structure or function of the body or mind

Disinfection process used to destroy microorganisms; destroys all pathogenic organisms except spores

Distribution movement of drugs by the circulatory system to the site of action

Disturbed sensory perception a state in which the individual or group experiences or is at risk for a change in the amount, pattern, or interpretation of incoming stimuli

Diversity welcoming individuals of different race, religion, nationality, culture, age, sexual orientation, and identity

Documentation written, legal record of all pertinent interventions with the patient—assessments, diagnoses, plans, interventions, and evaluations

Dominant group group within a culture that has the authority to control the value system and determine the rewards of the system; usually the largest group in a society

Donor person who donates blood or an organ to be given to another person

Do-not-hospitalize an order specifying that a patient, usually one who is terminally ill and anticipating death, not be admitted to the hospital in the event of a worsening of condition

Do-not-resuscitate (DNR) an order specifying that there be no attempt to resuscitate a patient in the event of cardiopulmonary arrest

Dosha patient's basic condition; understanding dosha is central to Ayurvedic medicine

Dressing protective covering placed over a wound

Droplet transmission transmission of particles greater than 5 mcm

Drug allergy hypersensitivity caused by previous exposure to a medication; may occur immediately or be delayed; manifestations range from mild to severe

Drug substance that modifies body functions when taken into the living organism; synonym for medication

Drug tolerance tendency of the body to become accustomed to a drug over time; larger doses are required to produce the desired effects

Dry powder inhalers (DPIs) types of breath-activated delivery methods for inhaled medications

Dynorphin the endorphin having the most potent analgesic effect

Dysfunctional grief abnormal or distorted grief that may be either unresolved or inhibited

Dysphagia difficulty in swallowing or inability to swallow

Dyspnea difficult or labored breathing

Dysrhythmia an abnormal cardiac rhythm

Dysuria difficulty in voiding; may or may not be associated with pain

E

Ecchymosis collection of blood in subcutaneous tissues that causes a purplish discoloration

Edema accumulation of fluid in extracellular spaces

Elder abuse (EA) intentional act or failure to act by a caregiver or another person in a relationship involving an expectation of trust that causes or creates a risk of harm to an older adult; includes physical abuse, sexual abuse/contact, emotional/psychological abuse, neglect, and financial abuse/exploitation

Elective surgery surgery that is recommended but can be omitted or delayed without catastrophe

Electrocardiogram (ECG; EKG) graphic record produced by the electrocardiograph

Electroencephalograph instrument that measures and records electric impulses of the brain

Electrolyte substance capable of breaking into ions and developing an electric charge when dissolved in solution

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Electromyograph (EMG) instrument that records muscle tone

Electronic health record (EHR) digital version of a patient's chart that may contain the patient's medical history, diagnoses, medications, treatment plans, immunization dates, allergies, radiology images, and laboratory and test results

Electronic medical record (EMR) computer-based record or data that can be distributed among many caregivers in a standardized format

Electrooculogram recording of the electric current or potential produced by eye movements

Embolism blocking of an artery by a blood clot or by other foreign matter brought to the site by the blood flow

Embolus blood clot, foreign body, or air in the circulatory system; plural form is emboli

Emergency health assessment type of rapid focused assessment conducted when addressing a life-threatening or unstable situation

Emergency surgery surgery that must be performed immediately to save the person's life or a body organ

emotional intelligence ability or skill to be intelligent about emotions, our own and those of others

Empathy (1) objective understanding of the way in which a patient sees their situation, identifying with the way another person feels, putting oneself in another person's circumstances and imagining what it would be like to share that person's feelings; (2) intellectually identifying with the way another person feels

Endemic something that occurs with predictability in one specific region or population and can appear in a different geographical location

Endogenous infection in which the causative organism comes from microbial life harbored within the person

Endorphins morphine-like substances released by the body that appear to alter the perception of pain

Endoscopy direct visualization of hollow organs of the body using an endoscope (a flexible, lighted tube)

Endotracheal tube polyvinyl-chloride airway that is inserted through the nose or the mouth into the trachea, using a laryngoscope as a guide

Enema introduction of solution into the lower bowel

Enkephalins opioids that are widespread throughout the brain and dorsal horn of the spinal cord and are believed to reduce pain sensation by inhibiting the release of substance P

Enteral nutrition alternate form of feeding that involves passing a tube into the gastrointestinal tract to allow instillation of the appropriate formula

Entitlement reform proposed legislation making changes in entitlement benefits, such as Medicare and Medicaid, paid by the government to citizens, with the goal of improving the nation's budget

Entry phase phase of the home visit in which the nurse develops rapport with the patient and family members, mutually determines outcomes, makes assessments, plans and implements prescribed care, and provides teaching

Enuresis involuntary urination; most often used to refer to a child who involuntarily urinates during the night

Environmental health that aspect of human health determined by physical, chemical, biologic, and psychosocial factors in the environment

Epidermis superficial layer of the skin

Epidural analgesia means of providing pain relief with an opioid injection delivered by way of a catheter inserted in the midlumbar region into the epidural space

Epigenetics study of the changes that occur in organisms due to modification of gene expression and hereditability

Epigenomics epigenetic changes that occur in many genes or the entire organism

Epithelialization stage of wound healing in which epithelial cells form across the surface of a wound; tissue color ranges from the color of "ground glass" to pink

Equity equity ensures that individuals are provided the resources they need to have access to the same opportunities, as the general population. While equity represents impartiality, that is, the distribution is made in such a way to even opportunities for all the people. Conversely equality indicates uniformity, where everything is evenly distributed among people.

Erection condition that results when erectile tissue of the penis fills with blood as a result of stimulation

Ergonomics practice of designing equipment and work tasks to conform to the capability of the worker and providing a means for adjusting the work environment and work practices to prevent injuries

Erogenous zones areas of the body that produce sexual desire and arousal when stimulated

Erythema redness of the skin

Eschar thick, leathery scab or dry crust that is necrotic and must be removed for adequate healing to occur

Ethical dilemma situation that arises when attempted adherence to basic ethical principles results in two conflicting courses of action

Ethical distress occurrence when the nurse knows the right thing to do but either personal or institutional factors make it difficult to follow the correct course of action

Ethically and legally skilled capable of conducting oneself in a manner consistent with a personal moral code and professional role responsibilities

Ethics system dealing with standards of character and behavior related to what is right and wrong

Ethnicity sense of identification that a cultural group collectively has; the sharing of common and unique cultural and social beliefs and behavior patterns, including language and dialect, religious practices, literature, folklore, music, political interests, food preferences, and employment patterns

Ethnocentrism belief that one's own ideas, beliefs, and practices are best, superior, or most preferred to those of others; using one's cultural norms as the standard to evaluate others' beliefs

Ethnopharmacology study of the effect of ethnicity on responses to prescribed medication, especially drug absorption, metabolism, distribution, and excretion

Euphoria unrealistic sense of well-being

Eupnea normal respirations

Euthanasia mercy killing; the deliberate termination of the life of a person

Evaluating measurement of the extent to which the patient has achieved the goals specified in the plan of care; factors that positively or negatively influence goal achievement are identified, and the plan of care is terminated or revised

Evaluative statement a judgment summarizing the nurse's findings after data have been collected and interpreted to determine patient outcome achievement

Evidence-based practice (EBP) nursing care provided that is supported by sound scientific rationale

Evidence-based practice guideline guidelines written by a panel of experts that synthesize information from multiple studies and recommend best practices to treat patients with a disease, a symptom, or a disability

Evisceration protrusion of viscera through an incision

Exacerbation period in chronic illness when the symptoms of the disease reappear

Excretion removal of a drug from the body

Exercise active exertion of muscles involving the contraction and relaxation of muscle groups

Exogenous infection in which the causative organism is acquired from outside the host

Expected outcome specific, measurable criteria used to evaluate whether the patient goal has been met

Expectorant drug that facilitates the removal of respiratory secretions

Expert witness nurse who explains to the judge and jury what happened based on the patient's record and who offers an opinion as to whether the nursing care met acceptable standards of practice

Expiration act of breathing out; synonym for exhalation

Explicit power power obtained by virtue of a person's position

Extended family nuclear family and other related people

Extended-care facility includes residential care and intermediate or skilled long-term care facility

Extended-care services organizations, family members, and other caregivers that provide medical and nonmedical care for people with chronic illnesses or disabilities who are physically or mentally unable to care for themselves independently

External condom catheter soft, pliable sheath made of silicone material applied externally to the penis

Extracellular fluid (ECF) fluid outside the cells; includes intravascular and interstitial fluids

Exudate fluid that accumulates in a wound; may contain serum, cellular debris, bacteria, and white blood cells

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

F

Fact witness nurse who has knowledge of the actual incident prompting a legal case; bases testimony on firsthand knowledge of the incident, not on assumptions

Failure to thrive (FTT) physical and developmental retardation of infants or children resulting from physical or emotional neglect

Faith (1) spiritual dimensions of a person's life regardless of religious affiliation; (2) confident belief in something for which there is no proof or material evidence

False self a sense of self that might develop in individuals who have the emotional need to respond to the needs and ambitions that significant people, such as parents, have for them

Family any group of people who live together and depend on one another for physical, emotional, or financial support

Fasting state abstinence from food and fluids

Fear a feeling of dread; a cognitive response to a known threat

Febrile condition in which the body temperature is elevated

Fecal impaction collection in the rectum of hardened feces that cannot be passed

Fecal incontinence involuntary or inappropriate passing of stool or flatus

Feces intestinal waste products

Fee for service system in which a bill is generated and a fee is paid every time a provider does something for a patient

Feedback verbal and nonverbal evidence that the message is received and understood

Felony (1) crime punishable by imprisonment in a state or federal penitentiary for more than 1 year; (2) crime of greater offense than a misdemeanor

Female genital mutilation (FGM) any procedure that involves partial or total removal of the external female genitalia or other injury to the female genital organs for nonmedical reasons

Feminist ethics type of ethical approach that aims to critique existing patterns of oppression and domination in society, especially as these affect women and the poor

Fever elevation above the upper limit of normal body temperature; synonym for pyrexia

Fiber all dietary plant material that is not digestible by the gastrointestinal tract, enzymes, and secretions

Fidelity keeping promises and commitments made to others

Fight-or-flight response the body preparing itself against threat, to either resist (fight) or evade (flight) the danger

Filtration passage of a fluid through a permeable membrane whose spaces do not allow certain solutes to pass; passage is from an area of higher pressure to one of lower pressure

Fissure a linear break on the margin of the anus

Fistula an abnormal passage from an internal organ to the skin or from one internal organ to another

Flaccidity decreased muscle tone; synonym for hypotonicity

Flatulence excessive formation of gases in the gastrointestinal tract

Flatus intestinal gas

Flexibility ability to use a muscle through its entire range of motion

Flexion the action of bending or the condition of being bent, especially the bending of a limb or joint.

Flow sheets graphic record of abbreviated aspects of the patient's condition (e.g., vital signs, routine aspects of care)

Fluid balance state in which water and its solutes in the body are in normal proportions and concentrations and are in appropriate body compartments

Fluid imbalance state in which water and its solutes in the body are in improper proportions and concentrations or are improperly located in body compartments

Fluid volume deficit deficiency in the amount of both water and electrolytes in extracellular fluid; water and electrolyte proportions remain near normal

Fluid volume excess excessive retention of water and sodium in extracellular fluid in near-normal proportions

Flushing red appearance of the skin

Focus charting a documentation system that replaces the problem list with a focus column that incorporates many aspects of a patient and patient care; the focus may be a patient strength or a problem or need; the narrative portion of focus charting uses the data (D), action (A), response (R) format

Focused health assessment assessment is conducted to assess a specific problem; focuses on pertinent history and body regions but may also be used to address the immediate and highest priority concerns for an individual patient

Foley catheter indwelling or retention catheter that remains in place to drain urine

Footdrop complication resulting from extended plantar flexion

Formal teaching planned teaching based on learner objectives

Frail-old term for people over age 75; the fastest-growing segment of the population

Fraud willful and purposeful misrepresentation that could cause, or has caused, loss or harm to people or property

Fremitus vibration of the chest wall that can be palpated during the physical examination

Frequency increased incidence of voiding

Friction occurs when two surfaces rub against each other; the resulting injury resembles an abrasion and can also damage superficial blood vessels directly under the skin

Friction rub crackling sounds heard in the chest cavity caused by inflamed pleura rubbing against the chest wall

Full liquid diet diet that contains milk, plain frozen desserts, pasteurized eggs, cereal gruels, and milk and egg substitutes in addition to clear liquids; contains liquids that can be poured at room temperature

Functional health level of health defined by one's ability to carry out usual and desired daily activities

Functional incontinence state in which a person experiences an involuntary, unpredictable passage of urine

Fungi plant-like organisms (molds and yeasts) that can cause infection

G

Gastric residual feeding remaining in the stomach

Gastrostomy opening created into the stomach

Gate control theory theory that explains that excitatory pain stimuli carried by small-diameter nerve fibers can be blocked by inhibiting signals carried by large-diameter nerve fibers

Gay term used to describe homosexual males

Gender dysphoria diagnosis for a person whose biologic sex at birth is contrary to the one with which the person identifies

Gender identity the inner sense a person has of being male or female, which may be the same as or different from biologic sex; synonym for sexual identity

Gender nonconformity behaving and appearing in ways that are considered atypical for a person's biologic sex

Gender role behavior the behavior a person conveys about being male or female, which may or may not be the same as biologic sex or gender identity

General adaptation syndrome (GAS) biochemical model of stress describing the body's general response to stress

General anesthesia administration of drugs by the inhalation or intravenous (IV) route to produce central nervous system depression; a combination of both intravenous and inhalation anesthetics that allows for rapid induction, excretion, and reversal of effects

Generic name name assigned by the manufacturer who first develops a drug; it is often derived from the chemical name

Genome all the DNA in an organism, including its genes

Genomics (1) study of the structure and interactions of all genes in the human body, including their interactions with each other as well as the environment; (2) emerging discipline in which genomic information about a person is used in their clinical care (e.g., for diagnostic or therapeutic decision making)

Gerontologic nursing nursing specialty concerned with the care of the older adult

Gerontology study of all aspects of the aging process and their consequences

Gerotranscendence transformation of an older adult's view of reality from a rational, social, individually focused, materialistic perspective to a more transcendent vision manifested by maturity, wisdom, spirituality, and a decreased

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

emphasis on superficial relationships

Gingivitis inflammation of the gingivae or gums

Global self term used to describe the composite of all the basic facts, qualities, traits, images, and feelings one holds about oneself

Glossitis inflammation of the tongue

Glycosuria presence of sugar in the urine

Goal an aim or an end

Good Samaritan law law that holds certain health practitioners blameless when undertaking to aid a person in an emergency

Gram-negative bacteria bacteria with chemically more complex cell walls that can be decolorized by alcohol

Gram-positive bacteria bacteria with a thick cell wall that resists decolorization (loss of color) and are stained violet

Granulation tissue new tissue that is pink/red in color and composed of fibroblasts and small blood vessels that fill an open wound when it starts to heal

Graphic record form used to record specific patient variables

Grief emotional response to loss. Dysfunctional grief: distorted or abnormal grief response, including inhibited grief (suppression of grief reaction) and unresolved grief (lengthy or denied grief reaction). Abbreviated grief: short but genuine grief reaction. Anticipatory grief: grief reaction before actual loss.

Ground conducting connection between a source of electricity and the earth

Group dynamics study of a group's characteristics and ways of functioning

Growth an increase in body size or changes in body cell structure, function, and complexity

Guided imagery using all five senses to imagine an event or body process unfolding according to a plan, focusing on evoking pleasant images to replace negative or stressful feelings and to promote relaxation

Gurgles continuous musical sounds that are audible in expiration or inspiration, or both; formerly called rhonchi

Gustatory pertaining to taste

H

Half-life the amount of time it takes for half a dose of a drug to be eliminated from the body

Halitosis offensive breath

Handoff a nurse's report to another nurse or health care provider about a patient's status and progress

Healing touch (HT) uses a collection of energy techniques to assess and treat the human energy system, thereby affecting physical, emotional, mental, and spiritual health and healing

Health care–associated infection (HAI) an infection that was not present on admission to a health care institution and develops during the course of treatment for other conditions (nosocomial)

Health disparity a specific difference that is closely linked to social, economic, and/or environmental disadvantage

Health equity attainment of the highest level of health for all people

Health history a collection of subjective information that provides information about the patient's health status

Health information exchange (HIE) an electronic system that allows physicians, nurses, pharmacists, other health care providers, and patients to appropriately access and securely share a patient's vital medical information

Health insurance marketplace federal and state system designed to help people more easily find health insurance that fits their budget and needs with a plan offering comprehensive coverage, from doctors to medications to hospital visits; insurance options can be compared based on price, benefits, quality, and other features described in plain language

Health literacy ability to read, understand, and act on health information

Health maintenance organization (HMO) prepaid, group-managed care plan that allows subscribers to receive all the medical services they require through a group of affiliated providers; there may be no additional out-of-pocket costs, or subscribers may pay only a small fee, called a copayment

Health problem condition related to health requiring intervention if disease or illness is to be prevented or resolved and coping and wellness are to be promoted

Health promotion behavior of an individual motivated by a personal desire to increase well-being and health potential

Health state of optimal functioning or well-being

Health-belief model what people believe to be true about themselves in relation to health

Healthy nurse ANA defines a healthy nurse as one who actively focuses on creating and maintaining a balance and synergy of physical, intellectual, emotional, social, spiritual, personal and professional well-being. Healthy nurses live life to the fullest capacity, across the wellness/illness continuum, as they become stronger role models, advocates, and educators, personally, for their families, their communities and work environments, and ultimately for their patients.

Helping relationship interaction that sets the climate of movement of the participants toward common goals

Hematoma localized mass of usually clotted blood

Hematuria blood in the urine; if present in large enough quantities, urine may be bright red or reddish brown

Hemolysis process of freeing a red blood cell of its hemoglobin by destruction of the cell membrane

Hemoptysis sputum-containing blood

Hemorrhage excessive blood loss due to the escape of blood from blood vessels

Hemorrhoids abnormally distended rectal veins

Hemothorax blood that develops in the pleural space

Heparin lock intravenous needle or catheter with an injection pad attached at the end

Heredity passing on of physical or mental characteristics genetically from one generation to another

Hesitancy delay or difficulty in initiating voiding

Heterosexuality having sexual feelings for a person of the opposite sex

Hierarchy of needs as defined by Maslow, certain needs are more basic than others; a person strives to at least minimally meet certain needs before attending to others

High-level wellness functioning to one's maximum potential while maintaining balance and purposeful direction in the environment

High-reliability organization organization that operates in a complex, high-hazard domain for an extended period without serious accidents or catastrophic failures

HIPAA privacy rule federal law enacted to ensure that health information is protected while allowing the flow of health information needed to provide and promote high-quality health care and to protect the public's health and well-being

Holism theory and philosophy that focuses on connections and interactions between parts of the whole

Holistic health care health care that takes into account the whole person interacting in the environment

Holistic nursing nursing practice built on a holistic philosophy

Home health care agency agency eligible to receive federal funds that provides home-based health care; may be independent, hospital operated, or health department managed

Home health care health care services provided in a patient's home

Homeopathy practice of medicine based on the belief of supporting the body while the symptoms are allowed to "run their course" to stimulate and strengthen the immune system and promote healing

Homeostasis various physiologic and psychological mechanisms respond to changes in the internal and external environment to maintain a balanced state

Homosexuality having sexual feelings for a person of the same sex

Hope ingredient in life responsible for a positive outlook, even in life's bleakest moments

Horizontal violence anger and aggressive behavior between nurses or nurse-to-nurse hostility

Hospice a type of end-of-life care for persons who are terminally ill, characterized by the following: (1) patients are kept as free of pain as possible so that they may die comfortably and with dignity; (2) patients receive continuity of care, are not abandoned, and do not lose personal identity;
(3) patients retain as much control as possible over decisions regarding their care and are allowed to refuse further life-prolonging technologic interventions; and (4) patients are viewed as individuals with personal fears, thoughts, feelings, values, and hopes

Hospitals acute-care settings that provide various health care services, such as emergency care, inpatient care, surgery,

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

diagnostic tests, and patient education

Host animal or person on or within which microorganisms live

Hydration union of a substance with water; term often is used as the opposite of dehydration, in which case it means that there is normal intracellular and extracellular water volume

Hydrometer instrument used to determine the specific gravity of urine

Hydrostatic pressure force exerted by a fluid against the container wall

Hypercalcemia excess of calcium in the extracellular fluid

Hyperkalemia excess of potassium in the extracellular fluid

Hypermagnesemia excess of magnesium in the extracellular fluid

Hypernatremia excess of sodium in the extracellular fluid

Hyperphosphatemia above-normal serum concentration of inorganic phosphorus

Hyperpyrexia high fever, above 41°C (105.8°F)

Hypersomnia condition characterized by excessive sleeping, especially daytime sleeping

Hypertension blood pressure elevated above the upper limit of normal

Hyperthermia high body temperature

Hypertonic having a greater concentration than the solution with which it is being compared

Hyperventilation condition in which there is more than the normal amount of air entering and leaving the lungs

Hypervolemia excess of plasma

Hypnotic pharmaceutical agent used to induce sleep

Hypocalcemia insufficient amount of calcium in the extracellular fluid

Hypokalemia insufficient amount of potassium in the extracellular fluid

Hypomagnesemia insufficient amount of magnesium in the extracellular fluid

Hyponatremia insufficient amount of sodium in the extracellular fluid

Hypophosphatemia below-normal serum concentration of inorganic phosphorus

Hypoproteinemia insufficient amount of protein substances in the extracellular fluid

Hypotension blood pressure below the lower limit of normal

Hypothermia low body temperature

Hypotonic having a lesser concentration than the solution with which it is being compared

Hypoventilation decreased rate or depth of air movement into the lungs

Hypovolemia deficiency of blood plasma

Hypovolemic shock shock due to a decrease in blood volume

Hypoxemia deficient oxygenation of blood

Hypoxia inadequate amount of oxygen available to the cells

I

Iatrogenic infection infection that occurs as a result of a treatment or diagnostic procedure

Ideal self self a person would like to be or thinks one should be; includes aspirations, moral ideas, and values

Identity diffusion failure to integrate various childhood identifications into a harmonious adult psychosocial identity

Idiosyncratic effect unusual, unexpected response to a drug that may manifest itself by overresponse, underresponse, or response different from the expected outcome

Ileal conduit urinary diversion in which the ureters are connected to the ileum with a stoma created on the abdominal wall

Ileostomy opening into the small intestine allows fecal content from the ileum to be eliminated through the stoma

Illness abnormal process in which any aspect of the person's functioning is altered (in comparison to the previous

condition of health)

Imagery using all five senses to imagine an event or body process unfolding according to a plan

Immunization process of rendering a person immune or resistant to particular antigenic agents or bacteria

Implement carry out the plan of care

Implied power power obtained by force of a person's personality that might enable that person to have more power to influence others than designated leaders

Impotence condition in which a man is unable to attain or maintain an erection to such an extent that he cannot have satisfactory sexual intercourse; synonym for erectile failure

Incentive spirometer equipment to help maximize lung inflation

Incident report (or variance report) a report of any event that is not consistent with the routine operation of the health care facility that results in or has the potential to result in harm to a patient, employee, or visitor

Incision wound made with a sharp cutting instrument

Incivility rude, intimidating, and undesirable behavior directed at another person

Inclusion giving everyone a sense of purpose and belonging, a feeling of being valued

Incontinence inability to voluntarily control the discharge of urine or feces

Incontinence-associated dermatitis moisture-associated skin breakdown caused by prolonged contact of the skin with urine or feces

Incontinent experiencing involuntary or uncontrolled loss of urine or feces

Independent action (1) nursing action carried out at the instruction or order of a nurse; (2) actions within the legal scope of nursing's independent domain; synonym for nurse-initiated or nurse-prescribed intervention

Indirect care intervention treatment performed away from the patient but on behalf of a patient or group of patients

Indirect contact personal contact with either a vector, a living creature that transmits an infectious agent to a human, usually an insect; or an inanimate object, called a fomite, such as equipment or countertops

Inductive reasoning cognitive process in which one identifies a specific idea or action and then makes conclusions about general ideas

Indwelling urethral catheter catheter that remains in place for continuous urine drainage; synonym for Foley catheter

Infancy period from 1 month to 1 year of age

Infection disease state resulting from pathogens in or on the body

Inference the judgment reached about a cue

Infiltration escape of fluid into subcutaneous tissue

Inflammatory response localized response of the body to injury or infection; protective mechanism that eliminates invading pathogens and allows for tissue repair to occur

Informal teaching unplanned teaching sessions dealing with the patient's immediate learning needs and concerns

Informed consent knowledgeable, voluntary permission obtained from a patient to perform a specific test or procedure

Inhalation (1) act of breathing in; synonym for inspiration; (2) administration of a drug in solution via the respiratory tract

Initial assessment comprehensive nursing assessment resulting in baseline data that enable the nurse to make a judgment about a patient's health status, ability to manage one's own health care, and need for nursing, and to plan individualized, holistic health care for the patient

Initial planning planning that addresses each problem listed in the prioritized nursing diagnoses and identifies appropriate patient goals and the related nursing care

Injection introduction of medication into the body by a syringe attached to a needle

Inpatient person who enters a health care setting for a stay ranging from 24 hours to many years

Insomnia difficulty in falling asleep, intermittent sleep, or early awakening from sleep

Inspection purposeful and systematic observation

Inspiration act of breathing in; synonym for inhalation

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Institutional racism the systematic distribution of resources, power and opportunity in our society to the benefit of people who are white and the exclusion of people of color

Instructional materials objects or vehicles used to communicate information that supplements the teaching method

Instrumental activities of daily living (IADLs) the activities of daily living needed for independent living

Integrative health combination of complementary health and conventional health approaches in a coordinated way

Integument skin

Integumentary system skin and its appendages (i.e., hair, glands in the skin, and nails)

Intercessory prayer involves praying for the benefit of another person to the Judeo-Christian God

Intercourse (coitus or copulation) insertion of the penis into the partner's vagina, anus, or mouth

Interdependent action nursing action performed by the nurse in collaboration with other members of the health care team

Intermittent fever body temperature that alternates between fever and normal or subnormal temperature

Intermittent pulse normal pulse rhythm broken by periods of irregular rhythm

Intermittent urethral catheter straight catheter used to drain the bladder for short periods (5 to 10 minutes)

Internal respiration exchange of oxygen and carbon dioxide between the circulating blood and tissue cells

Interoperability ability of a system to exchange electronic health information with and use electronic health information from other systems without special effort on the part of the user

Interpersonal communication communication that occurs between two or more people with a goal to exchange messages

Interpersonally skilled capable of establishing and maintaining caring relationships that facilitate the achievement of valued goals while simultaneously affirming the worth of the participants in the relationship

Intersectionality occurs when race, sex, gender, class, and other individual characteristics intersect and overlap with one another, often leading to an increased burden of discrimination on several fronts and other negative outcomes

Intersectionality the simultaneous experience of categorical and hierarchical classifications including but not limited to race, class, gender, sexuality, and nationality

Interstitial fluid fluid between the cells

Intervention any action performed to modify an expectation or to enhance outcomes

Interview planned communication for a specific purpose (e.g., data collection)

Interviewing techniques communication skills specifically designed to gather and validate information

Intimate partner violence (IPV) domestic violence or battering between two people in a close relationship

Intracellular fluid (ICF) fluid within the cell; synonym for cellular fluid

Intractable pain severe pain that is extremely resistant to relief measures

Intradermal injection injection placed just below the epidermis

Intramuscular (IM) injection an injection into deep muscle tissue, usually of the buttock, thigh, or upper arm

Intraoperative phase period lasting from admission to the operating room area to transfer to the postoperative recovery area after surgery is completed

Intrapersonal communication communication techniques or self-talk to enhance positive interaction with the patient and family

Intravascular fluid fluid within the vascular system; synonym for plasma

Intravenous (IV) infusion injection of relatively large quantities of solution into a vein

Intravenous (IV) route injection of a solution into the vein

Intuitive problem solving direct understanding of a situation based on a background of experience, knowledge, and skill that makes expert decision making possible

Ion atom or molecule carrying an electric charge in solution

Irrigation flushing of a tube, canal, or area with solution

ISBAR communication a process for effective handoff communication among health care professionals about a

patient's condition, standing for Identity/Introduction, Situation, Background, Assessment, Recommendation, and Read back

ISBARQ revised SBAR approach that includes Introduction, Situation, Background, Assessment, Recommendations, and Question and answer

Ischemia deficiency of blood in a particular area

Isokinetic exercise exercise involving muscle contractions with resistance varying at a constant rate

Isolation protective procedure designed to prevent the transmission of specific microorganisms; also called protective aseptic techniques and barrier techniques

Isometric exercise exercise in which muscle tension occurs without a significant change in muscle length

Isotonic exercise movement in which muscles shorten (contract) and move

Isotonic having about the same concentration as the solution with which it is being compared

J

Jaundice yellow appearance of the skin

Just culture refers to an organization's commitment to accountability and a focus supporting universal safety in health care

Justice process that distributes benefits, risks, and costs fairly

K

Kardex care plan trade name for a care plan documentation system that encompasses (1) prescriptions for nursing care related to activities of daily living; (2) nursing diagnoses and related patient goals and nursing orders; and (3) the nursing care related to diagnostic measures and the medical regimen

Kegel exercises repetitious contraction and relaxation of the pubococcygeal muscle to improve vaginal tone and urinary continence

Ketosis an abnormal accumulation of ketone bodies that is frequently associated with acidosis

Kinesthesia awareness of positioning of body parts and body movement

Korotkoff sounds series of sounds that correspond to changes in blood flow through an artery as pressure is released

Kussmaul's respiration breathing an extreme rate and depth of breathing

L

Laissez-faire leadership leadership style in which the leader relinquishes all power to the group

Language prescribed way of using words; a means to express thoughts and feelings

Lateral violence verbal, emotional, or physically abusive behavior of a registered nurse toward another staff member

Law rule of conduct established and enforced by the government of a society

Lawsuit legal action in a court of law

Laxative drug used to induce emptying of the intestinal tract

Leadership ability to direct or motivate others toward the achievement of predetermined goals

Learning increasing one's knowledge; having one's behavior changed in a measurable way as a result of an experience

Learning readiness patient's willingness to engage in the teaching–learning process (emotional readiness) and experiential readiness to begin the challenge of learning

Lesbian term for a homosexual female

Liability legal responsibility for one's acts (and failure to act); includes responsibility for financial restitution of harms resulting from negligent acts

Licensure to be given a license to practice nursing in a state or province after successfully meeting requirements

Life review/reminiscence universal phenomenon identified by Butler as a review of one's life through one's recollections

Ligaments tough, fibrous bands that bind joints together and connect bones and cartilage

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Line of gravity vertical line that passes through the center of gravity

Linguistic competence ability of caregivers and organizations to understand and effectively respond to the linguistic needs of patients and their families in a health care encounter

Lipid group name for fatty substances, including fats, oils, waxes, and related compounds

Literacy ability to read and write

Litigation process of lawsuit

Living will advance directive specifying the medical care a person would want or refuse should that person lack the capacity to consent to or refuse treatment

Local adaptation syndrome (LAS) localized response of the body to stress, precipitated by trauma or pathology

Local anesthesia injection of an anesthetic agent such as bupivacaine, lidocaine, or tetracaine to a specific area of the body for minor, short-term surgical, or diagnostic procedures; bathes the tissue around a targeted nerve or infiltrates the underlying tissue in the operative area

Localized symptoms symptoms that are limited or restricted to a discrete area

Long-term care facilities for long-term care that provide health care and help with activities of daily living for people of any age who are physically or mentally unable to independently care for themselves

Loss inaccessibility or change in a valued person, object, or situation. Actual loss: loss tangible to both the person sustaining the loss and to others. Perceived loss: loss tangible only to the person sustaining it. Physical loss: loss of life, limb, an object, person, pet, or job. Psychological loss: loss that affects a person's self-image. Anticipatory loss: loss behaviors displayed before the actual loss occurs.

Love and belonging needs understanding and acceptance of others in giving and receiving love

M

Maceration softening through liquid; overhydration

Macromineral mineral that is needed by the body in amount greater than 100 mg/day

Macronutrient essential nutrient that supplies energy and builds tissue such as carbohydrate, fat, and protein

Macroshock electric current passing through a relatively large area of a person

Malpractice act of negligence as applied to a professional person such as a physician, nurse, or dentist

Managed care an organized, high-quality, cost-effective system of health care that influences the selection and use of health care services of a population

Management the act of planning, organizing, directing, and controlling available human resources and financial resources to deliver quality care to patients and families

Masturbation self-stimulation for sexual satisfaction

Maturational loss the loss experienced as a result of natural developmental processes

Meaningful use the use of certified electronic health record technology to achieve health and efficiency goals, with a financial incentive from Medicare and Medicaid

Medicaid Title XIX (Social Security Act, 1965) to make health care available to those people with less than the minimum income who do not qualify for Medicare

Medical asepsis practices designed to reduce the number and transfer of pathogens; synonym for clean technique

Medical diagnosis statement about a specific disease process using terminology from a well-developed classification system accepted by the medical profession

Medical home an enhanced model of primary care that provides whole-person, accessible, comprehensive, ongoing, and coordinated patient-centered care

Medical neighborhood a patient-centered medical home and the constellation of other clinicians providing health care services to patients within it, along with community and social service organizations and state and local public health facilities

Medicare Title XVIII (Social Security Act, 1965) to provide a measure of health coverage to all Social Security recipients

Medication administration record (MAR) the patient's medication record must include documentation of all the

medications administered to the patient (drug, dose, route, time), the nurse administering the drug, and, for some medications (e.g., analgesics), the reason the drug was administered and its effectiveness.

Medication reconciliation process of creating an accurate list of all medications a patient is taking, including drug name, dosage, frequency, and route, and comparing the list to the physician's admission, transfer, or discharge orders, with the goal of providing correct medications to the patient at all transition points within the hospital

Medication record record documenting all medications administered to the patient, the nurse administering the drugs, and sometimes the reason the drug was administered and its effectiveness

Medication substance that modifies body functions when taken into living organisms; synonym for drug

Melatonin a natural chemical produced at night that decreases wakefulness and promotes sleep

Menarche initiation of the menstrual cycle

Meniscus curved surface at the top of a column of liquid in a tube

Menopause decrease of cyclic hormonal production and cessation of menses in females, usually between ages 45 and 60 years

Menstruation periodic discharge of bloody secretions through the vagina; usually for 4 to 5 days each month

Mentorship relationship in which an experienced person (the mentor) advises and assists a less experienced person

Meridian part of an intricate structure of 72 energy circuits that nourish and support all cells and organs of the body, through which qi flows vertically in the body

Message term used in communication theory to denote the actual physical product of the source or encoder (e.g., a speech, interview, phone conversation, chart)

Metabolic acidosis proportionate deficiency of bicarbonate ions in the extracellular fluid

Metabolic alkalosis proportionate excess of bicarbonate ions in the extracellular fluid

Metabolism (1) chemical changes in the body by which energy is provided; (2) breakdown of a drug to an inactive form; also referred to as biotransformation

Metered dose inhaler (MDI) instrument that delivers a controlled dose of medication to narrowed airways with each compression of the canister

Micromineral mineral or trace element that is needed by the body in an amount less than 100 mg/day

Micronutrient vitamin or mineral needed in much smaller amount to regulate and control body processes

Microshock electric current passing through a relatively small area of a person, usually part of the heart

Micturition process of emptying the bladder; urination; voiding

Middle adult the adult between the ages of 40 and 60 years; also called middle adulthood

Midlife crisis realization that the halfway point in life has been reached and youthful goals may not have been achieved

Mindfulness capacity to intentionally bring awareness to present-moment experience with an attitude of openness and curiosity; mindfulness promotes healing as you pause, focus on the present, and listen

Minerals inorganic elements found in nature

Mini-infusion pump battery-operated pump for intermittent infusion allowing medication mixed in a syringe to be connected to the primary line and delivered by mechanical pressure applied to the syringe plunger

Minimum data set a standard established by health care institutions that specifies the information that must be collected from every patient

Minority group group having some physical or cultural characteristic that identifies the people within the group as different from the dominant culture

Misdemeanor crime of lesser offense than a felony and punishable by fines, imprisonment (usually for less than 1 year), or both

Mixed incontinence symptoms of urge and stress incontinence are present, although one type may predominate

Moderate sedation/analgesia (conscious or procedural sedation) used for short-term and minimally invasive procedures

Modulation process by which the sensation of pain is inhibited or modified

MOLST form stands for Medical Order for Life-Sustaining Treatment, a medical order indicating a patient's wishes

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

regarding treatments commonly used in a medical crisis

Moral agency ability to behave in an ethical way; to do the ethically right thing because it is the right thing to do

Moral agency for the professional nurse, moral agency is the capacity to be trusted to meet the reasonable expectations of the publics we serve, as articulated in the American Nurses' Association's Social Policy statement and Code of Ethics

Moral development influence of cultural effects on one's perceptions of justice in interpersonal relationships

Moral injury an injury that occurs when there has been: (1) a betrayal of what is right, (2) by someone who holds legitimate authority, or by oneself, (3) in a high-stakes situation.

Moral resilience developed capacity to respond well to morally distressing experiences and to emerge strong

Morals like ethics, concerned with what constitutes right action; more informal and personal than the term ethics

Morbidity frequency that a disease occurs

Mortality number of deaths

Mourning period during which a person learns to accept grief

Multipayer system a health care system in which care is paid for by both private insurance companies and the government

Multispecialty practice group organization of physicians from different specialties joined to share income, expenses, facilities, equipment, and support staff; the group practice can better provide comprehensive care

Myocardial infarction one type of acute coronary syndrome characterized by the death of heart tissue due to lack of oxygen; also known as a heart attack

N

Narcolepsy condition characterized by an uncontrolled desire to sleep

Narrative descriptive record of the patient's condition; includes patient's response to interventions by health professionals and patient's progress toward goal achievement

Narrative notes progress notes written by nurses in a source-oriented record

Nasal cannula disposable, plastic device that delivers oxygen via two protruding prongs for insertion into the nostrils

Nasogastric (NG) tube tube inserted through the nose and into the stomach

Nasointestinal (NI) tube tube inserted through the nose and into the upper portion of the small intestine

National Database of Nursing Quality Indicators (NDNQI) ANA-funded database of nursing-sensitive quality indicators aimed at promoting and facilitating the standardization of information submitted by hospitals across the United States on nursing quality and patient outcomes

National Medical Care health care services in Canada, funded by taxes and provided to every Canadian citizen

Naturopathic medicine a relatively new system of medicine that is not only a system of medicine but also a way of life, with emphasis on patient responsibility, patient education, health maintenance, and disease prevention

Nebulizer instrument that disperses fine particles of medication into the deeper passages of the respiratory tract where absorption occurs

Necrosis death of cells and tissue

Negative nitrogen balance condition resulting in muscle wasting and decreased physical energy for movement and work (e.g., anorexia nervosa and certain cancers)

Negative reinforcement an ineffective teaching strategy that uses criticism or punishment

Negative-pressure wound therapy (NPWT) activity that promotes wound healing and wound closure through the application of uniform negative pressure on the wound bed, reduction in bacteria in the wound, and the removal of excess wound fluid

Negativism negative verbalizations and behaviors

Negligence performing an act that a reasonably prudent person under similar circumstances would not do, or failing to perform an act that a reasonably prudent person under similar circumstances would do

Neonate period from birth to 28 days of age

Nephrotoxic capable of causing kidney damage

Neuromodulator endogenous opioid chemical regulators that appear to have analgesic activity and alter pain perception

Neurons nerve cells, which conduct impulses from one part of the body to another

Neuropathic pain pain that results as a direct consequence of a lesion or disease affecting abnormal functioning of the peripheral nervous system (PNS) or central nervous system (CNS)

Neurotransmitters substances that either excite or inhibit target nerve cells

Never events serious but preventable surgical errors (that should never occur)

Nociceptive pain pain from a normal process that results in noxious stimuli being perceived as painful

Nociceptors pain receptors

Nocturia excessive urination during the night

Nocturnal myoclonus condition characterized by marked muscle contraction that results in the jerking of one or both legs during sleep

Noise factors that distort the quality of a message and interfere with the communication process

Noncompliance nonadherence to a therapeutic recommendation

Nonmaleficence principle of avoiding evil

Nonproductive cough forceful expiratory effort without production of mucus; also called a dry cough

Non–rapid eye movement sleep (NREM) non–rapid eye movement that characterizes four stages of sleep

Nonverbal communication exchange of information without the use of words

Normal flora microorganisms that normally inhabit various body sites and are part of the body's natural defense system

Nosocomial infection hospital-acquired infection

Nosocomial something originating or taking place in the hospital (i.e., infection)

NPO nothing by mouth (Latin: nil per os)

Nuclear family family unit, family of marriage, parenthood, or procreation, and their immediate children

Nuclear terrorism intentional dispersal of radioactive materials into the environment for the purpose of causing injury and death

Nurse coach a registered nurse who integrates coaching competencies into any setting or specialty area of practice to facilitate a process of change or development that assists individuals or groups to realize their potential

Nurse healer a nurse who facilitates another person's growth toward wholeness (body–mind–spirit) or who assists another with recovery from illness or transition to peaceful death

Nurse navigator clinically trained nurse responsible for the identification and removal of barriers to timely and appropriate treatment

Nurse practice act law established to regulate nursing practice

Nurse Practice Act each state has a nurse practice act that protects the public by broadly defining the legal scope of nursing practice.

Nurse-initiated intervention independent nursing actions that involve carrying out nurse-prescribed interventions written on the nursing care plan, as well as any other actions that nurses initiate without the direction or supervision of another health care professional and that result from their assessment of patient needs

Nursing actions any action performed by a nurse to assist patients to meet health goals: promote wellness, prevent disease or illness, restore health, or facilitate coping with altered functioning

Nursing audit method of evaluating the outcomes of nursing care or the process by which these outcomes are achieved using a review of patient records

Nursing care conference formal meeting of nurses to discuss some aspect of patient's care

Nursing care plan written guide to direct the efforts of the nursing team as they work with the patient to meet health goals; specifies prioritized nursing diagnoses, patient goals, and nursing orders

Nursing care rounds procedure in which a group of nurses visit patients individually at bedside to gather information that helps to plan and to evaluate nursing care

Nursing diagnosis actual or potential health problem that an independent nursing intervention can prevent or resolve (actual problem is present; possible problem may be present, but more data are needed to confirm or disconfirm the

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

problem; and potential problem may occur); defining characteristics are present as risk factors

Nursing ethics a subset of bioethics; formal study of ethical issues that arise in the practice of nursing and of the analysis used by nurses to make ethical judgments

Nursing history assessment of the patient by interview to identify the patient's health status, strengths, health problems, health risks, and need for nursing care

Nursing informatics specialty that integrates nursing science, computer science, and information science to manage and communicate data, information, and knowledge in nursing practice

Nursing intervention any treatment, based on clinical judgment and knowledge, that a nurse performs to enhance patient outcomes; there are nurse-initiated, physician-initiated, and collaborative interventions

Nursing Interventions Classification (NIC) first comprehensive, validated list of nursing interventions applicable to all settings that can be used by nurses in multiple specialties and facilitates the work of identifying appropriate interventions

Nursing order prescribes the nursing care to be given to assist patient to meet health goals

Nursing Outcomes Classification (NOC) developed by the Iowa Outcomes Project and presents the first comprehensive standardized language used to describe the patient outcomes that are responsive to nursing intervention

Nursing process five-step systematic method for giving patient care; involves assessing, diagnosing, planning, implementing, and evaluating

Nursing profession that focuses on the holistic person receiving health care services and provides a unique contribution to the prevention of illness and maintenance of health

Nursing research encompasses both research to improve the care of people in the clinical setting and to study people and the nursing profession, including education, policy development, ethics, and nursing history

Nursing theory differentiates nursing from other disciplines and activities by serving the purposes of describing, explaining, predicting, and controlling desired outcomes of nursing care practices

Nursing workflow set of tasks, sequenced and grouped chronologically into processes, and the set of people or resources needed for those tasks, that are necessary to accomplish a given goal; examples would be all the tasks included, in sequence, that a nurse goes through to take a patient's blood pressure, administer a unit of packed red blood cells, or admit a new patient onto a medical/surgical unit

Nursing-sensitive quality indicators indicators specific to nursing that identify structures of care and care processes that influence care outcome

Nutrients specific biochemical substances used by the body for growth, development, activity, reproduction, lactation, health maintenance, and recovery from illness or injury

Nutrition study of the nutrients and how they are handled by the body, as well as the impact of human behavior and environment on the process of nourishment

O

Obesity weight greater than 20% above ideal body weight

Objective data information perceptible to the senses; may be verified by another person

Observation conscious and deliberate use of the five senses to gather data

Obstructive sleep apnea in adults, five or more predominantly obstructive respiratory events (the absence of breathing [apnea] or diminished breathing efforts [hypopnea] or respiratory effort-related arousals) during sleep, accompanied by sleepiness, fatigue, insomnia, snoring, subjective nocturnal respiratory disturbance, or observed apnea and associated health disorders (hypertension, coronary artery disease, atrial fibrillation, congestive heart failure, stroke, diabetes, cognitive dysfunction, or mood disorder)

Occult blood blood present in such minute quantities that it cannot be detected with the unassisted eye

Occupational Safety and Health Administration (OSHA) government facility that establishes minimum health and safety standards for workers

Occurrence charting (or variance charting) documentation when a patient fails to meet an expected outcome or a planned intervention is not implemented, including the unexpected event, the cause of the event, actions taken in response to the event, and discharge planning, when appropriate; typically used for variances that affect quality, cost, or length of stay

Official name name by which a drug is identified in official publications

Older adult refers to adults over age of 65

Old-old term used to describe adults over age 75; sometimes referred to as frail-old

Olfactory pertaining to smell

Oliguria scanty or greatly diminished amount of urine voided in a given time; 24-hour urine output is 100 to 400 mL

Oncotic pressure pressure exerted by plasma proteins on permeable membranes in the body; synonym for colloid osmotic pressure

Ongoing partial health assessment also known as a follow-up assessment, it is one that is conducted at regular intervals during care of the patient; concentrates on identified health problems to monitor positive or negative changes and evaluate the effectiveness of interventions

Ongoing planning planning carried out by any nurse who interacts with the patient to keep the plan up to date, to facilitate the resolution of health problems, to manage risk factors, and to promote function

Opioid more correct term for narcotic analgesics, since these drugs act by binding to opiate receptor sites in the central nervous system

Opportunist bacteria that may potentially be harmful

Optimization strategies to improve processes, maximize effective use, reduce errors, reduce costs, eliminate workflow inefficiencies, improve clinical decision support, and improve end-user skills and satisfaction with the system

Organism a living being

Organizational communication process of communication that involves individuals and groups to achieve established goals

Orgasm apex of sexual activity in which rhythmic contractions of the genital organs and many other physiologic changes occur

Orthopedics the correction or prevention of disorders of body structures used in locomotion

Orthopnea type of dyspnea in which breathing is easier when the patient sits or stands

Orthostatic hypotension temporary fall in blood pressure associated with assuming an upright position; synonym for postural hypotension

Osmolarity concentration of particles in a solution, or a solution's pulling power

Osmosis passage of a solvent through a semipermeable membrane from an area of lesser concentration to an area of greater concentration until equilibrium is established

Osmotic pressure drawing power for water or the attraction for water exerted by solute particles

Osteoporosis condition characterized by loss of calcium from bone tissue

Ostomy general term referring to an artificial opening; usually used to refer to an opening created for the excretion of body wastes

Outcome and Assessment Information Set (OASIS) assessment instrument representing core items of a comprehensive assessment for adult nonmaternity home health care patients that forms the basis for measuring patient outcomes for the purpose of improving the quality of care provided

Outcome end product of nursing care; patient outcomes are measurable changes in patient behavior or state of health

Outcome evaluation evaluation that focuses on measurable changes in the health status of the patient or the end results of nursing care

Outcome identification observation of the patient to demonstrate the resolution of the problems identified by the nursing diagnoses and general problem list, along with the time frame for accomplishing these outcomes

Outpatient person who requires health care services but does not need to stay in an institution for those services

Overflow incontinence involuntary loss of urine associated with overdistention and overflow of the bladder

Overhydration above-normal amounts of water in extracellular spaces

Ovulation discharge of ovum from the ovary at about the midpoint of each menstrual cycle

Ovum female reproductive cell, often called an egg

Oxygenation the process of providing cells life-sustaining oxygen

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

P

2010 federal legislation designed for comprehensive health reform, with an intent to expand coverage, control health care costs, and improve the health care delivery system

Pacemaker another name for the sinoatrial (SA) node; initiates the transmission of electrical impulses, causing contraction of the heart at regular intervals

Pain sensation of physical or mental suffering or hurt that usually causes distress or agony to the one experiencing it

Pain threshold amount of stimulation required before a person experiences the sensation of pain

Pain tolerance point beyond which a person is no longer willing to endure pain (i.e., pain of greater duration or intensity)

Palliative care hospice care; taking care of the whole person—body, mind, spirit, heart, and soul—with the goal of giving patients with life-threatening illnesses the best quality of life they can have through the aggressive management of symptoms

Palliative sedation the lowering of patient consciousness with medication for the express purpose of limiting the patient's awareness of suffering that is intractable and intolerable

Pallor paleness of the skin

Palpation method of examining by feeling a part of the body with the fingers or hand

Palpitation perception of one's own heartbeat

Paracentesis withdrawal of fluid from a body cavity, usually from the abdominal cavity

Paralysis absence of strength secondary to nervous impairment

Paralytic ileus paralysis of intestinal peristalsis

Paraplegia paralysis of the legs

Parasite organism that lives on or in a host and relies on it for nourishment

Parasomnia patterns of waking behavior that appear during sleep (e.g., sleep walking, sleep talking, nocturnal erections)

Parenteral nutrition nourishment provided via IV therapy

Parenteral outside of intestines or alimentary canal; popularly used to refer to injection routes

Paresis impaired muscle strength or weakness

Paresthesia numbness and tingling

Partial peripheral nutrition (PPN) nutrition prescribed for patients who require nutrient supplementation through a peripheral vein because they have an inadequate intake of oral feedings

Passive exercise manual or mechanical means of moving the joints

Paternalism an action that is based on what a parent would do

Pathogen disease-producing microorganism

Patient care ergonomics practice of designing equipment and work tasks to conform to the capability of the worker in relation to patient care

Patient education process of influencing the patient's behavior to effect changes in knowledge, attitudes, and skills needed to maintain and improve health

Patient goal statement describing an expected patient outcome

Patient handoff transferring responsibility for a patient from one caregiver to another with the goal of providing timely, accurate information about a patient's plan of care, treatment, current condition, and anticipated changes

Patient navigator person without a clinical background (e.g., a lay person or a social worker) who assists the patient with scheduling, financial assistance, psychosocial support, and community support

Patient outcome expected conclusion to a patient health problem, or in the event of a wellness diagnosis, an expected conclusion to a patient's health expectation

Patient portal web-based tool with secure access that allows patients to communicate with and receive information from their health care providers

Patient Protection and Affordable Care Act (PPACA)

Patient record a compilation of a patient's health information; the patient record is the only permanent legal document that details the nurse's interactions with the patient

Patient the person receiving care

Patient-Centered Assessment Method (PCAM) tool for assessing patient complexity using the social determinants of health that often explain why patients with the same or similar health conditions differ in their ability to manage their health and in their outcomes

Patient-controlled analgesia (PCA) method of controlling pain that involves an infusion pump that holds a vial of an IV analgesic that the patient controls and self-administers in small doses

Pay for performance a strategy using financial incentives to reward providers for achieving a range of payer objectives, including delivery efficiencies, submission of data and measures to the payer, and improved quality and patient safety

Peak level highest plasma concentration of a drug

Pedagogy science of teaching that generally refers to the teaching of children and adolescents

Pediculosis infestation with lice

Peer review evaluation at the closest point to the patient and an ongoing tool to use for professional growth

Perceived loss loss of youth, of financial independence, and of a valued environment experienced by a person, but intangible to others

Perception conscious process of organizing and interpreting data from the senses into meaningful information

Percussion act of striking one object against another for the purpose of producing a sound; used to assess the location, shape, size, and density of body tissues

Percutaneous endoscopic gastrostomy (PEG) surgically (open or laparoscopically) placed gastrostomy tube

Performance improvement commitment to healthier patients, quality care, reduced costs, and making a difference; accomplished by discovering a problem, planning a strategy, implementing a change, and assessing the change to see if the goal is met

Perfusion process by which oxygenated blood passes through body tissues

Periodontitis (periodontal disease) marked inflammation of the gums that also involves degeneration of the dental periosteum (tissues) and bone

Perioperative nursing wide variety of nursing activities carried out before, during, and after surgery

Perioperative phase the three phases of perioperative patient care that include the preoperative, intraoperative, and postoperative phases

Peripheral parenteral nutrition (PPN) prescribed for patients who require nutrient supplementation through a peripheral vein because they have an inadequate intake of oral feedings

Peripheral resistance restraint to blood flow created by arteriole walls in a partial state of contraction

Peripherally inserted central catheter (PICC) type of venous access device that can be introduced into a peripheral vein and advanced as far as the superior vena cava

Peristalsis involuntary, progressive, wave-like movement of the musculature of the gastrointestinal tract

Personal health records (PHRs) information sheets that contain the individual's medical history, including diagnoses, symptoms, and medications

Personal identity an individual's conscious sense of who they are

Personal protective equipment (PPE) gloves, gowns, masks, and protective eye gear designed to minimize or prevent the health care worker's exposure to infectious material

Personal space external environment surrounding a person that is regarded as being part of that person

Person-centered care model of patient care based on holistic roots in which the nurse or other caregiver uses every clinical encounter to assess how the person is doing and to communicate respect, compassion, and care

Petechiae small, purplish hemorrhagic spots on the skin that do not blanch with applied pressure

pH expression of hydrogen ion concentration and resulting acidity of a substance

Phagocytosis engulfing of microorganisms, foreign particles, or other cells by phagocytes

Phantom pain sensation of pain without demonstrable physiologic or pathologic substance; commonly observed after the amputation of a limb

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Pharmacodynamics process by which drugs alter cell physiology and affect the body

Pharmacogenetics the study of how genetic variation affects an individual's response to drugs

Pharmacogenomics use of information about a person's genetic makeup, or genome, to choose the drugs and drug doses that are likely to work best for that person

Pharmacokinetics movement of drug molecules in the body in relation to the drug's absorption, distribution, metabolism, and excretion

Pharmacology study of actions of chemicals on living organisms

Pharmacotherapeutics dynamic that achieves the desired therapeutic effect of the drug without causing other undesirable effects

Philosophy study of wisdom, fundamental knowledge, and the processes we use to develop and construct our perceptions of life

Phlebitis inflammation of a vein

Phlegm thick, respiratory secretions

Physical assessment systematic examination of the patient for objective data to better define the patient's condition and to help the nurse in planning care, usually performed in a head-to-toe format; a collection of objective data about changes in the patient's body systems

Physical dependence phenomenon in which the body physiologically becomes accustomed to an opioid and suffers withdrawal symptoms if the opioid is suddenly removed or the dose is rapidly decreased

Physician-initiated intervention dependent nursing actions, involving carrying out physician-prescribed orders

Physiologic needs need for oxygen, food, water, temperature, elimination, sexuality, activity, and rest; these needs have the highest priority and are essential for survival

PIE charting documentation system that does not develop a separate care plan; the care plan is incorporated into the progress notes in which problems are identified by number, worked up using the problem (P)–intervention (I)–evaluation (E) format, and evaluated each shift

Piggyback infusion intermittent IV administration of medications through a primary IV line, with the additive container positioned higher than the primary IV solution

Placebo Latin word meaning, "I shall please"; an inactive substance that gives satisfaction to the person using it

Plaintiff person or government bringing a lawsuit against another

Plan establish patient goals to prevent, reduce, or resolve the problems identified in the nursing diagnoses and determination of related nursing interventions

Plan of nursing care written guide that directs the efforts of the nursing team as the nurses work with patients to meet health goals; it specifies nursing diagnoses, outcomes, and associated nursing interventions

Planned change change agent's purposeful, systematic effort to bring about change

Plaque invisible, destructive, bacterial film that builds up on teeth and eventually leads to the destruction of tooth enamel

Plasma liquid constituent of blood; synonym for intravascular fluid

Pleurae two-layered membranes; the visceral pleura covers the lungs, and the parietal pleura lines the thoracic cavity

Pleural effusion fluid in the pleural space

Pleural friction rub continuous, dry grating sound caused by inflammation of pleural surfaces and loss of lubricating pleural fluid

Pneumonia inflammation or infection of the lungs

Pneumothorax air in the pleural space

Podiatrist one who treats foot disorders; synonym for chiropodist

Poison control center facility that handles poison exposure and provides poison prevention teaching to the general population

POLST form stands for Physician Order for Life-Sustaining Treatment, a medical order indicating a patient's wishes regarding treatments commonly used in a medical crisis; must be completed and signed by a health care professional, not the patient

Polyp tumor on a stem that bleeds easily and may become malignant

Polypharmacy the use of many medications at the same time

Polysomnography sleep study consisting of an electroencephalographic recording of the stages of sleep and any episodes of apnea, continuous monitoring of arterial oxygen saturation, and an electrocardiographic recording to detect any cardiac dysrhythmias

Polyuria excessive output of urine (diuresis)

Positive reinforcement affirmation of the efforts of patients

Possible nursing diagnoses statements describing a suspected problem for which additional data are needed to confirm or rule out the suspected problem

Possible problems problems the patient may experience if certain trends in the patient's condition continue unreversed

Postanesthesia care unit (PACU) an area often adjacent to the surgical suite designed to provide care for patients recovering from anesthesia or moderate sedation/analgesia

Postoperative phase period lasting from admission to the recovery area through recovery and convalescence

Postural hypotension temporary fall in blood pressure associated with assuming an upright position; synonym for orthostatic hypotension

Postvoid residual (PVR) urine that remains in the bladder after the act of micturition; a synonym for residual urine

Power ability to influence others to achieve a desired effect

Preceptorship process by which an experienced person facilitates an orientee's introduction to new responsibilities through teaching and guidance

Precordium anterior surface of the chest wall overlying the heart and its related structures

Predictive analytics variety of statistical techniques that analyze current and historical facts to make predictions about future or otherwise unknown events

Pre-entry phase phase of the home visit in which the nurse collects information about the patient's health care needs, gathers needed supplies, and evaluates safety factors

Preferred provider organization (PPO) a prepaid group practice that allows a third-party payer (such as an insurance company) to contract with a group of health care providers to administer services at a lower fee in return for prompt payment and a guaranteed volume of patients and services

Premenstrual (tension) syndrome (PMS) menstrual cycle–related distress; occurs a few days before the onset of menstruation

Preoperative phase period lasting from the decision that surgery is necessary until the patient is transferred to the operating room area

Presbycusis age-related hearing loss in which there is decreased ability to distinguish higher frequencies

Presbyopia condition of aging in which decreased elasticity of the eye lens hinders accommodation to close vision

Preschooler period from ages 3 to 6 years

Prescription used by physician to convey medication plans for a patient

Presencing standing in the presence of another consciously believing in—and affirming—their capacity for wholeness

Pressure injury (1) localized damage to the skin and underlying tissue that usually occurs over a bony prominence or is related to the use of a (medical or other) device; (2) any lesion caused by unrelieved pressure that results in damage to underlying tissue; formerly known as pressure ulcer

Primary health care essential health care based on practical, scientifically sound, and socially acceptable methods and technology, made universally accessible through the community's full participation and at a cost the community can afford

Primary preventive care care directed toward health promotion and specific protection against illness

Principle-based approach an approach to bioethics that offers specific action guides

PRN order "as needed" order for medication

Problem-oriented medical record (POR) documentation system organized according to the person's specific health problems; includes database, problem list, plan of care, and progress notes

Process evaluation evaluation focusing on the nature and sequence of activities carried out by nurses implementing the

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

nursing process

Process series of actions, changes, or functions to bring about a result

Productive cough cough that produces respiratory tract secretions (sputum)

Profession an occupation that meets specific criteria including a well-defined body of specific and unique knowledge, a code of ethics and standards, ongoing research, and autonomy

Professionalism a way of being/commitment to secure the interests and welfare of those entrusted to one's care

Progress notes any of a variety of methods of notes that relate how a patient is progressing toward expected outcomes

Proprioception description of the sense, usually at a subconscious level, of the movements and position of the body, especially its limbs, independent of vision

Protein vital component of every living cell; composed of carbon, hydrogen, oxygen, and nitrogen

Proteinuria albumin in the urine; indication of kidney disease

Protocol written plan that details the nursing activities to be executed in specific situations

Psychogenic pain pain for which no physical cause can be identified

Psychological loss loss caused by an altered self-image

Psychomotor learning acquisition of physical skills

Psychosomatic disorder physiologic alterations and illness believed to be due to psychological influences

Puberty period during which primary and secondary sexual characteristics develop and the capability of sexual reproduction is attained

Public health facilities local, state, provincial, or federal facilities that provide public health services to members of communities

Pulmonary ventilation movement of air into and out of the lungs

Pulse deficit difference between the apical and radial pulse rates

Pulse oximetry noninvasive technique that measures the oxygen saturation (SaO2) of arterial blood

Pulse pressure difference between systolic and diastolic pressures

Pulse wave produced in the wall of an artery with each beat of the heart

Purposeful rounding proactive, systematic, nurse-driven, evidence-based intervention that helps nurses anticipate and address patient needs

Purulent containing pus

Purulent drainage comprised of white blood cells, liquefied dead tissue debris, and both dead and live bacteria

Pyorrhea extensive inflammation of the gums and alveolar tissues; synonym for periodontitis

Pyrexia elevation above the upper limit of normal body temperature; synonym for fever

Pyuria pus in the urine; urine appears cloudy

Q

Qi gong system of posture, exercise (both gentle and dynamic), breathing techniques, and visualization that regulates the qi

Qi represents an invisible flow of energy that circulates through plants, animals, and people, as well as the earth and sky

QSEN stands for Quality and Safety Education for Nurses, a project for preparing future nurses with the knowledge, skills, and attitudes (KSAs) necessary to continuously improve the quality and safety of the health care systems within which they work

Qualitative research method of research conducted to gain insight by discovering meanings

Quality assurance program ongoing evaluation program designed and implemented to secure the excellence of health care; may involve an assessment of structure, process, and outcome standards

Quality improvement the commitment and approach used to continuously improve every process in every part of an organization, with the intent of meeting and exceeding customer expectations and outcomes—also known as continuous quality improvement (CQI) or total quality management (TQM)

Quantitative research research involving the concepts of basic and applied research

Quantum leadership leadership that moves beyond the traditional modes previously experienced by all levels of workers; spawned by the impact of the information age on work and the worker

Quick priority assessments (QPAs) are short, focused, prioritized assessments you do to gain the most important patient information you need to have first.

R

Race division of human beings based on distinct physical characteristics

Racism a belief that race is the primary determinant of human traits and capabilities and the racial differences produce an inherent superiority of a particular race; racial prejudice or discrimination

Radiography examination by x-ray film

Range of motion complete extent of movement of which a joint is normally capable

Rape sexual violation of a person by someone who uses force, threats, and abuse

Rapid eye movement sleep (REM) stage that constitutes 20% to 25% of a person's nightly sleep; person is difficult to arouse during this stage

Rapport feeling of mutual trust experienced by people in a satisfactory relationship

Reactive hyperemia the body's flooding of an area with blood after it has suffered from poor circulation for a period; the occurrence of a blanchable reddening of the skin when pressure is removed

Read back a process in which a nurse or other health care provider repeats a verbal order back to a physician to ensure that it was correctly heard and interpreted

Reality orientation method of care used to promote awareness of reality in confused or disoriented patients

Receiver (decoder) term used in communication theory that specifies the person or object to which the message is directed

Reception process of receiving data about the internal or external environment through the senses

Reciprocity process allowing a nurse to apply for and be endorsed as a registered nurse by another state

Recommended dietary allowance (RDA) recommendations for average daily amounts of essential nutrients that healthy population groups should consume over time

Referral process of sending or guiding someone to another source for assistance

Referral source a person who recommends home health care services and supplies the home health care facility with details about the patient's needs

Referred pain pain in an area removed from that in which stimulation has its origin

Reflective practice occurs when the caregiver has a profound awareness of self, and one's own biases, prejudgments, prejudices, and assumptions, and understands how these may affect the therapeutic relationship

Reflex incontinence emptying of the bladder without the sensation of the need to void

Reflex pain response automatic response of the central nervous system to the stimulus of pain

Regional anesthesia anesthetic agent injected near a nerve or nerve pathway in or around the operative site, inhibiting the transmission of sensory stimuli to central nervous system receptors; the patient remains awake but loses sensation in a specific area or region of the body

Regression behavior that is more characteristic of an earlier age

Rehabilitation centers centers specializing in services for patients requiring physical or emotional rehabilitation and for treatment of any type of drug dependency

Rehabilitation process of restoring a person's highest level of possible wellness and returning that person's ability to live and to work as normally as possible after a disabling illness or injury

Reimbursement source entity that pays for home health care services

Relationship interaction of people over time

Relaxation response an alert, hypometabolic state of decreased sympathetic nervous system arousal, which can also be viewed as the opposite of Selye's general adaptation syndrome response

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Religion organized system of beliefs about a higher power; often includes set forms of worship, spiritual practices, and codes of conduct

REM rapid eye movement that characterizes the dream state of sleep

Remission period in a chronic illness when the disease is present, but the person does not experience symptoms of the disease

Reporting oral, written, or computer-based communication of patient data with the purpose of informing others

Repression exclusion of an anxiety-producing event from conscious awareness

Research process that uses observable and verifiable information (data), collected in a systematic manner, to describe, explain, or predict events

Research utilization (RU) is a process of transforming research knowledge into practice, with knowledge referring to both conducting and analyzing research. It enables nurses to improve patient care by informing practice on interventions that may no longer be useful.

Reservoir natural habitat for the growth and multiplication of microorganisms

Residual urine urine that remains in the bladder after the act of micturition

Resilience hopeful attitude, utilizing healthy internal coping mechanisms and external resources, such as supportive work environments, mindfulness-based stress reduction training, and assertive communication skills training

Resource allocation decision making about fair and equitable distribution of scarce resources

Respiration gas exchange between the atmospheric air in the alveoli and blood in the capillaries

Respiratory acidosis proportionate excess of carbonic acid in the extracellular fluid

Respiratory alkalosis proportionate deficiency of carbonic acid in the extracellular fluid

Respite care a type of care provided for caregivers of homebound ill, disabled, or older adult patients

Rest condition in which the body is in a decreased state of activity, with the consequent feeling of being refreshed

Restless legs syndrome (RLS) a condition in which patients are unable to lie still and report experiencing unpleasant creeping, crawling, or tingling sensations in the legs

Restraint device used to limit movement or immobilize a patient

Retention inability to void although urine is produced by the kidneys and enters the bladder; excessive storage of urine in the bladder

Retention sutures sutures used to provide extra support in wounds in obese patients or in wounds with increased risk of dehiscence

Reticular activating system (RAS) network of neurons in the core of the brainstem, with ascending and descending tracts to other areas of the brain that monitor and regulate incoming sensory stimuli and level of arousal

Retrospective audit evaluation of nursing care and patient outcomes after the patient has been discharged (may use postdischarge questionnaires, patient interviews, or chart review)

Retrospective evaluation evaluation of nursing care and patient outcomes after the patient has been discharged using postdischarge questionnaires, patient interviews, or chart review to collect data

Review of systems (ROS) physical examination of all body systems in a systematic manner as part of the nursing assessment

Risk factor something that increases a person's chance for illness or injury

Risk nursing diagnoses clinical judgments that an individual, family, or community is more vulnerable to develop the problem than others in the same or similar situation

Role performance ability to successfully execute societal expectations regarding role-specific behaviors

Root cause analysis deep investigation into a sentinel event to determine why the event occurred, and exploring the circumstances that led to it to determine where improvements can be made

S

Safety and security needs person's need to be protected from actual or potential harm and to have freedom from fear

Safety event report documentation describing any injury or potential for injury suffered by a patient in a health care facility

Sanguineous containing or mixed with blood

Sarcopenia loss of muscle mass that frequently occurs in older adults as part of the natural aging process

SBAR consistent, clear, structured, and easy-to-use method of communication between health care personnel; it organizes communication by the categories of: Situation, Background, Assessment, and Recommendations.

Scar connective tissue that fills a wound area

scholarly inquiry the logical, organized process of searching for answers to questions via research, assessment of findings from literature searches, and examination of other knowledge sources

School-age period from ages 6 to 12 years

Science a body of knowledge gained by observing, identifying, describing, investigating, and explaining events and occurrences that are perceived in the world

Scientific knowledge knowledge arrived at by applying scientific methods

Scientific problem solving systematic problem-solving process that involves (1) problem identification, (2) data collection, (3) hypothesis formulation, (4) plan of action, (5) hypothesis testing, (6) interpretation of results, and (7) evaluation resulting in conclusion or revision of the study

Scope of practice The American Nurses Association states that the Nursing Scope and Standards of Practice describe the "who," "what," "where," "when," "why," and "how" of nursing practice in keeping with the terms of their professional license.

Scrub nurse nurse who assists the surgeon during surgery, maintaining surgical asepsis while draping, handling instruments, and handling supplies

Scultetus binder type of bandage with multiple tails; synonym for many-tailed binder

Sebaceous gland gland found in the skin that secretes an oily substance called sebum

Secondary preventive care care directed either to health maintenance for patients experiencing health problems or to prevention of complications or disabilities

Secondary traumatic stress feeling of despair caused by the transfer of emotional distress from a victim to a caregiver, which often develops suddenly

Self-actualization needs highest level on the hierarchy of needs, which include the need for individuals to reach their full potential through development of their unique capabilities

Self-actualization reaching of one's potential through full development of one's unique capabilities

Self-compassion being kind and understanding when confronted with personal failings

Self-concept mental image or picture of self; includes body image, subjective self, ideal self, and social self

Self-esteem needs need to feel good about oneself and to believe others hold one in high regard

Self-esteem person's perception of one's total being, including self-worth and body image

Self-governance employing a decentralized organizational structure for decision making; self-governance at the unit level and respect for, and acknowledgment of, professional autonomy

Semantics study of the meaning of words

Semen seminal plasma containing sperm

Semipermeable membrane selectively permeable membrane that allows water to pass through it but is either impermeable or selectively permeable to solutes

Sensoristasis arousal state of the reticular activating system; general drive state

Sensory deficit impaired or absent functioning of one or more senses

Sensory deprivation condition resulting from decreased sensory input or input that is monotonous, unpatterned, or meaningless

Sensory overload condition resulting from excessive sensory input to which the brain is unable to meaningfully respond

Sensory perception conscious process of selecting, organizing, and interpreting data from the senses into meaningful information Sensory/perceptual alteration disturbance in the body's ability to receive or process data from its internal or external environment

Sensory poverty condition that results when one learns about the world without experiencing it up close, right here, right now

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Sensory processing disorder difficulty in the way the brain takes in, organizes, and uses sensory information, causing a person to have problems interacting effectively in the everyday environment

Sensory reception the process of receiving data about the internal or external environment through the senses

Sentinel event an unexpected occurrence involving death or serious physical or psychological injury, or the risk thereof

Separation anxiety condition that occurs when a child is afraid of being sent away from caregivers who are loved and who provide security

Serosanguineous drainage mixture of serum and red blood cells

Serous drainage composed of clear, serous portion of the blood and from serous membranes

Serous resembling blood serum; clear and watery in appearance

Servant leadership philosophy and set of practices that begins with the natural feeling of wanting to serve; its aim is to enrich the lives of individuals, build better organizations, and ultimately creates a more just and caring world

Set point level at which the hypothalamus attempts to maintain body temperature

Sexual dysfunction condition that prevents a person or couple from engaging in or obtaining satisfaction from sexual activity

Sexual harassment unwelcome verbal or physical advance or sexually explicit statement (e.g., leers, pats, grabs, jokes, requests for dates, and even rape) that interferes with one's ability to do one's job by making one feel humiliated, intimidated, or uncomfortable

Sexual health the integration of the somatic, emotional, intellectual, and social aspects of sexual being in ways that are positively enriching and that enhance personality, communication, and love

Sexual orientation preferred biologic sex of the partner of an individual

Sexuality degree to which a person exhibits and experiences maleness and femaleness physically, emotionally, and mentally

Sexually transmitted infection (or disease) (STI) disease that spreads from one person to another through intimate sexual contact

Shamanism belief that illness originates in the spirit world and usually involves a loss of power; treatment consists of first, restoring the individual's power, and second, treating symptoms

shared governance shared governance gives nurses more input and influence over their jobs and how the organization makes decisions that affect them. Every nurse brings their own wisdom, expertise and experience that are not leveraged enough if not tapped in to. Shared governance models ensure that every nurse has a voice.

Shearing force force created when layers of tissue move on one another

Shock body's reaction to acute peripheral circulatory failure due to an abnormality of circulatory control or to a loss of circulating fluid

Single-payer system health care system in which the government collects all health care fees via taxes and pays out all health care costs

Sinoatrial (SA) node a mass of tissue in the upper right atrium, just below the opening of the superior vena cava, that initiates the transmission of electrical impulses, causing contraction of the heart at regular intervals; also known as pacemaker

Situational awareness—from Endsley (1995): "the perception of the elements in the environment in a volume of time and space, the comprehension of their meaning and the projection of their status in the near future"

Situational crisis change that results when a person faces an event or situation that causes a disruption in one's life

Situational leadership theory of leadership that considers the leader's style, the work group's maturity, and the situation at hand to form a comprehensive approach to management style

Situational loss experienced as a result of an unpredictable event, including traumatic injury, disease, death, or national disaster

Sitz bath special type of bath that applies heated water to the pelvic or rectal area

Skin sutures used to approximate wound tissues and skin; may be silk, synthetic, wire, or metal staples

Skin tests tests to determine antigen–antibody reaction

Sleep cycle passage through the four stages of NREM sleep (I, II, III, IV), then reversal (IV, III, II), and finally, instead

of reentering stage I and awakening, entering REM sleep and returning to stage II

Sleep deprivation a decrease in the amount, consistency, and quality of sleep; results from decreased REM or NREM sleep

Sleep hygiene nonpharmacologic recommendations such as reviewing and changing lifestyles and environment that help an individual get a better night's sleep

Sleep state of altered consciousness throughout which varying degrees of stimuli preclude wakefulness

Small-group communication communication that occurs when two or more nurses interact with two or more individuals, allowing the members to achieve a goal through communication

SOAP format method of charting narrative progress notes; organizes data according to subjective information (S), objective information (O), assessment (A), and plan (P)

Social determinants of health conditions in the environments in which people are born, live, learn, work, play, worship, and age that affect a wide range of health, functioning, and quality of life outcomes and risks

Social isolation sense of aloneness because of decreasing relationships with others, resulting from attitudinal, geographic, financial, or illness-related factors

Social media web-based technologies that allow users to create, share, and participate in dialogue in virtual communities and networks

Social self way a person believes that others see oneself

Soft diet regular diet that has been modified to eliminate foods that are hard to digest and to chew, including those that are high in fiber, high in fat, and highly seasoned

Solute substance dissolved in a solution

Solvent liquid holding a substance in solution

Somatic pain pain originating in structures in the body's external wall

Somnambulism sleepwalking

Sordes accumulation of mucus and crust formation on the teeth and around the lips

Source (encoder) term used in communication theory to specify the one who prepares and sends a message to the receiver

Source-oriented record documentation system in which each health care group records data on its own separate form

Spasticity increased muscle tone

Specific gravity a characteristic of urine that can be determined with manufactured plastic strips or an instrument called a urinometer or hydrometer

Sperm male reproductive cell; synonym for spermatozoan

Spermicide chemical agent used to destroy sperm

Sphincter circular muscle that constricts a passage or closes a natural orifice

Spiritual beliefs practices associated with all aspects of a person's life, including health and illness, that address the invisible "spirit"—a creative, mysterious, guiding power

Spiritual distress an alteration in spiritual health (e.g., spiritual pain, alienation, anxiety, guilt, anger, loss, despair)

Spiritual healing movement toward integration, from brokenness to wholeness

Spiritual health condition that exists when the universal spiritual needs for meaning and purpose, love and belonging, and forgiveness are met

Spiritual need lack of anything necessary for spiritual health (e.g., meaning and purpose, love and relatedness, forgiveness)

Spirituality anything that pertains to a person's relationship with a nonmaterial life force or higher power

Spirometer instrument used to measure lung capacities and volumes; one type is used to encourage deep breathing (incentive spirometry)

Sputum respiratory secretion expelled by coughing or clearing the throat

Standard acceptable, expected level of performance established by authority, custom, or consent

Standard precautions CDC precautions used in the care of all patients regardless of their diagnosis or possible

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

infection status; this category combines universal and body substance precautions

Standard terminology in health care information technology (IT) standard and agreed upon terms used in an electronic health record to improve data trending and sharing; ANA approved nursing terminologies include those listed in Table 20–5

Standardized plan of care prepared plan of care that identifies the nursing diagnoses, patient goals, and related nursing orders common to a specific population (e.g., normal neonates) or problem

Standards for critical thinking clear, precise, specific, accurate, relevant, plausible, consistent, logical, deep, broad, complete, significant, adequate (for the purpose), and fair

Standards rules or guidelines that allow nurses to carry out professional roles, serving as protection for the nurse, the patient, and the institution where health care is given

Standing order document that details the nursing care to be implemented in specific nursing situations, frequently when a physician is not present; may expand scope of nursing responsibilities

Stat order single order carried out immediately

Statutory law law enacted by a legislative body

Stereognosis the sense that perceives the solidity of objects, their size, shape, and texture

Stereotyping assigning characteristics to a group of people without considering specific individuality

Sterilization (1) the process by which all microorganisms, including spores, are destroyed; (2) surgical procedure performed to render a person infertile

Stertorous breathing noisy respirations

Stimulus agent, act, or other influence capable of initiating a response by the nervous system

Stoma artificial opening for waste excretion located on the body surface

Stomatitis inflammation of the oral mucosa

Stool excreted feces

Strength (muscle) ability of the muscle to move actively against resistance

Stress condition in which the human system responds to change in its normal balanced state

Stress incontinence state in which the person experiences a loss of urine of less than 50 mL that occurs with increased abdominal pressure

Stressor anything causing a person to experience stress; change in the balanced state

Stridor harsh, high-pitched sound usually heard on inspiration when upper airways become narrowed

Structure evaluation focuses on the environment in which care is provided; also known as an audit

Subculture group of people with different interests or goals than the primary culture

Subcutaneous injection injection into the subcutaneous tissue that lies between the epidermis and the muscle

Subcutaneous tissue underlying layer that anchors the skin layers to the underlying tissues of the body

Subjective data (symptoms, covert data) information perceived only by the affected person

Subjective self how one sees oneself; who one thinks one is

Sublingual area in the mouth under the tongue

Sudden infant death syndrome (SIDS) sudden death of an infant under the age of 1 year when consideration of the infant's history, a postmortem examination, and investigation of the scene of the death fail to reveal a cause of death

Sudden unexplained infant death (SUID) a broad term for sudden infant deaths in which the manner and cause of death cannot readily be identified prior to an investigation

Sundowning syndrome describes a phenomenon when a person habitually becomes confused or disoriented with darkness

Superuser someone who has become a system expert and can navigate the electronic health record with ease as to enter and review patient data

Suppository oval- or cone-shaped substance that is inserted into a body cavity and that melts at body temperature

Suprapubic catheter catheter inserted into the bladder through a small abdominal incision above the pubic area

Surfactant detergent-like phospholipid that reduces surface tension of the fluid lining the alveoli

Surgical asepsis practices that render and keep objects and areas free from microorganisms; synonym for sterile technique

Susceptibility degree of resistance of a host to a pathogen

Symptom abnormality indicative of illness as experienced by the patient; synonym for subjective data

Syndrome (nursing diagnoses) cluster of actual or risk nursing diagnoses that are predicted to be present because of a certain event or situation

Synergistic effect combined effect of two or more drugs is greater than the effect of each drug alone

System development lifecycle (SDLC) development cycle for an information technology system that includes the following phases: (1) analyze and plan, (2) design, (3) test, (4) train, (5) implement, (6) maintain, and (7) evaluate

Systematic reviews summarized findings from multiple studies of a specific clinical practice question or topic that recommend practice changes and future directions for research; one of the strongest sources of evidence for evidence-based practice

Systemic symptoms symptoms manifested throughout the entire body

Systolic pressure highest point of pressure on arterial walls when the ventricles contract

T

Tachycardia rapid heart rate

Tachypnea rapid rate of breathing

Tactile pertaining to touch

Tartar hard deposit on the teeth near the gum line formed by plaque buildup and dead bacteria

Teaching method the way information is taught that brings the learner into contact with what is to be learned

Teaching planned method or series of methods used to help someone learn

Teaching–learning process process of patient teaching that encompasses critical steps necessary to provide teaching and to measure learning; the teaching–learning process models the nursing process

Technical competencies skills that enable a nurse to skillfully manipulate equipment in a manner conducive to achieving a desired goal

Telecare technologies that provide for patient safety and independence at home, such as health and fitness apps, sensors and tools that connect the patient with caregivers, digital medication reminder systems, and early warning and detection technologies

Telehealth use of electronic information and telecommunication technologies to provide care when the patient and the clinician are not in the same place at the same time

Telehealth use of electronic information and telecommunications technologies to support and promote long-distance clinical health care, patient and professional health-related education, public health, and health administration

Telemedicine use of telecommunications technologies to support the delivery of all types of medical, diagnostic, and treatment-related services, usually by physicians or nurse practitioners

Temperament person's style of approaching people, situations, or events

Temperature refers to the hotness or coldness of a substance

Tendons strong, flexible, inelastic fibrous bands that attach muscle to bone

Teratogenic known to have potential to cause developmental defects in the embryo or fetus

Terminal illness illness from which there is no reasonable expectation of recovery or cure

Terminal weaning withdrawal of life-sustaining therapy with the understanding that death may result, generally after a decision is made that the therapy in question is medically futile or disproportionately burdensome

Tertiary preventive care care directed at helping rehabilitate patients and restore them to a maximum level of functioning after an illness

Theory statement based on observed facts that explains or characterizes a process, an occurrence, or an event, but cannot be proved directly or absolutely as a fact

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Therapeutic range that concentration of drug in the blood serum that produces the desired effect without causing toxicity

Therapeutic relationship relationship between the caregiver and patient that is focused on promoting or restoring health and well-being of the patient

Therapeutic touch (TT) an alternative therapy that involves using one's hands to consciously direct an energy exchange from the practitioner to the patient to facilitate healing or pain relief

Third-space fluid shift distributional shift and trapping of body fluids into body spaces such as the pleural, peritoneal, or pericardial, or into the interstitial space (plasma-to-interstitial shift)

Thoracentesis aspiration of fluid or air from the pleural space

Thoughtful practice the care of a patient by a clinician who utilizes clinical reasoning and reflective practice to guide thoughtful actions and person-centered processes of care

Thrill abnormal tremor accompanying a vascular or cardiac murmur felt on palpation

Thrombophlebitis inflammation in a vein associated with thrombus formation

Thrombus blood clot; plural is thrombi

Time-lapsed assessment an assessment that is scheduled to compare a patient's current status to baseline data obtained earlier

Time-out component of the universal protocol, just prior to beginning a surgical procedure, to verify the patient's identity and the correct surgical site and procedure

Toddler period from ages 1 to 3 years

Tolerance occurrence of the body's becoming accustomed to an opioid and needing a larger dose each time for pain relief

Tonus normal, partially steady state of muscle contraction

Topical anesthesia substance sprayed, spread, or applied with a compress of drug-saturated gauze or cotton-tipped applicators to cause a loss of feeling and sensation occur in the specific area

Topical application application of a substance directly to a body surface

Tort wrong committed by a person against another person or that person's property

Total body water (TBW) total amount of water in the body, expressed as a percentage of body weight. The term total body fluid also is used; fluids usually are considered to include water and electrolytes

Total incontinence continuous and unpredictable loss of urine, resulting from surgery, trauma, or physical malformation

Total parenteral nutrition (TPN) nutritional therapy that bypasses the gastrointestinal tract for patients who are unable to take food orally; meets the patient's nutritional needs with a highly concentrated, hypertonic nutrient solution administered intravenously through a central vein

Toxic effects (toxicities) specific groups of symptoms related to drug therapy that carry risk for permanent damage or death

Trace elements minerals found in the body in quantities less than 5 g and needed in only small amounts (18 mg or less)

Tracheostomy artificial opening made in the trachea through which a tracheostomy tube is inserted

Tracheostomy tube curved tube inserted into an artificial opening made in the trachea that comes with varied angles and in multiple sizes

Trade name drug name selected and trademarked by the company marketing the drug; also called brand name or proprietary name

Traditional Chinese medicine (TCM) healing system that believes the interaction of people with their environment is most significant in creating health

Traditional family composed of a husband, wife, and their children, who live together in one home

Traditional knowledge knowledge passed down from generation to generation

Trans fat partially hydrogenated liquid oil; trans fat raises serum cholesterol

Transactional leadership leadership style based on maintaining control by rewarding good behavior and punishing negative or detrimental behavior

Transcultural nursing providing nursing care that is planned and implemented in a way that is sensitive to the needs of

individuals, families, and groups representing the diverse cultural populations within our society

Transduction activation of pain receptors

Transformational leadership type of leadership in which the person creates revolutionary change and commits to the personal and professional growth of self and others

Transgender an inclusive term used to describe those who feel that the sex assigned to them at birth incompletely describes or fails to describe them

Transient incontinence occurrence that appears suddenly and lasts for 6 months or less and usually is caused by treatable factors, such as confusion secondary to acute illness, infection, and as a result of medical treatment, such as the use of diuretics or intravenous fluid administration

Transmission conduction of pain sensations from the site of an injury or inflammation along clear and unclear pathways to the spinal cord and then on to higher centers

Transmission-based precautions CDC precautions used in patients known or suspected to be infected with pathogens that can be transmitted by airborne, droplet, or contact routes; used in addition to standard precautions

Transsexual person of a certain biologic sex with the feelings of the opposite sex

Transvestite individual who desires to take on the role or wear the clothes of the opposite sex

Trauma injury

Tremor involuntary muscular movements

Triage: quickly examining patients to determine the extent and severity of problems and recommending appropriate treatment.

Trial hearing of evidence in a legal case before a judge (and jury) with the intent of reaching a decision or verdict

Trial-and-error problem solving method of problem solving that involves testing any number of solutions until one is found that works for that particular problem

Triglycerides predominant form of fat in food and the major storage form of fat in the body

Trough level the point when a drug is at its lowest concentration

Turgor tension of the skin determined by its hydration

U

Unconscious or implicit bias prejudice in favor or against one thing, person or group as compared to another, in a way that is usually considered unfair. Unconscious bias occurs automatically as the brain makes quick judgments based on past experiences and backgrounds

Unilateral affecting or occurring on one side only

Universal precautions isolation system that considers blood, body fluids containing blood, semen, and vaginal secretions of all patients as potentially infective

Unlicensed assistive personnel (UAP) individual who is trained to function in an assistive role to the licensed registered nurse in the provision of patient activities as delegated by and under the supervision of the registered professional nurse

Urge incontinence state in which a person experiences involuntary passage of urine that occurs soon after a strong sense of urgency to void

Urgency strong desire to void

Urgent surgery surgery that is not an emergency, but must be done within a reasonably short time frame to preserve health

Urinary diversion surgical creation of an alternate route for excretion of urine

Urinary incontinence any involuntary loss of urine

Urinary retention inability to void although urine is produced by the kidneys and enters the bladder; excessive storage of urine in the bladder

Urinary sheath soft, pliable sheath made of silicone material that is applied externally to the penis and directs urine away from the body; also known as external condom catheter

Urination process of emptying the bladder; micturition; voiding

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Urine waste product excreted by the kidneys

Usability extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use

Utilitarian action-guiding theory of ethics that states that the rightness or wrongness of an action depends on the consequences of the action

V

Validation act of confirming or verifying

Valsalva maneuver forcible exhalation against a closed glottis, resulting in increased intrathoracic pressure

Value system organization of values ranked along a continuum of importance

Value-based purchasing program that measures, reports, and rewards excellence in health care delivery, taking into consideration access, price, quality, efficiency, and alignment of incentives

Values clarification process by which people come to understand their own values and value system

Values set of beliefs that are meaningful in life and that influence relationships with others

Variables factors in a research study

Variance charting documentation method in case management when a patient fails to meet an expected outcome or when a planned intervention is not implemented that records unexpected events, the cause for the event, actions taken in response to the event, and discharge planning when appropriate; typically used for variances that affect quality, coast, or length of stay; also called occurrence charting

Variance report tool used by health care facilities to document the occurrence of anything out of the ordinary that results in or has the potential to result in harm to a patient, employee, or visitor; also called an incident report or occurrence report

Varicosity swollen, twisted vein

Vector nonhuman carriers—such as mosquitoes, ticks, and lice—that transmit organisms from one host to another

Venous thromboembolism blood clot or foreign substance that is dislodged and travels through the bloodstream until it lodges in a smaller vessel

Ventilation exchange of gases

Ventricles lower chambers of the heart

Veracity truth telling

Verbal communication exchange of information using words

Vesicular breath sounds normal sound of respirations heard on auscultation over peripheral lung areas

Vial glass bottle with self-sealing stopper through which medication is removed; may be single or multiple dose

Virtues human excellences; cultivated dispositions of character and conduct that motivate and enable us to be good human beings

Virulence ability to produce disease

Virus smallest of all microorganisms; can be seen only by using an electron microscope

Visceral pain pain originating in the internal organs in the thorax, cranium, or abdomen

Visceral pertaining to inner organs

Visual pertaining to sight

Vital signs body temperature, pulse and respiratory rates, and blood pressure; synonym for cardinal signs

Vitamins organic substances needed by the body in small amounts to help regulate body processes; are susceptible to oxidation and destruction

Voiding process of emptying the bladder; also called micturition or urination

Volume-control administration set intermittent intravenous medication infusion diluted with a small amount of solution

Voluntary facilities community facilities that are often funded by private donations, grants, or fund-raising and that provide a wide variety of direct services and education

Vulnerable population disadvantaged subsegment of a community requiring utmost care, specific ancillary considerations, and augmented protection in research; includes those living in poverty, women, children, older adults, rural and inner-city residents, new immigrants, the homeless, mentally ill patients, and people with disabilities and special health care needs

W

Waist circumference a numerical measurement of the waist, used to assess an individual's abdominal fat and establish ideal body weight

Wellness an active process in which an individual progresses toward the maximum possible potential, regardless of current state of health

Wellness diagnosis clinical judgment about an individual, family, or community in transition from a specific level of wellness to a higher level of wellness

Wheeze continuous, high-pitched squeak or musical sound made as air moves through narrowed or partially obstructed airway passages

Whistle-blowing term generally used to refer to employees who report their employers' violation of the law to appropriate law enforcement agencies outside the employers' facilities Whistle-blowing: Speaking up when witnessing actions that place patients at risk

Wound injury that results in a disruption in the normal continuity of a body tissue

X

X-ray high-energy electromagnetic wave capable of penetrating solid matter and acting on photographic film; synonym for roentgen ray

Y

Yin-yang energy forces in Chinese teaching that must be in balance for good health; expression of strong emotions results in disharmony and imbalance between these forces

Young adult adult between the ages of 20 and 40 years

Z

Z-track technique used to administer medications intramuscularly that ensures that the medication does not leak back along the needle track and into the subcutaneous tissue, reducing pain and discomfort

APPENDIX A
GUIDELINES FOR DELEGATION DECISION MAKING

INTRODUCTION

Delegation is the process for a nurse to direct another person to perform nursing tasks and activities (American Nurses Association [ANA] & National Council of State Boards of Nursing [NCSBN], 2019). Delegation involves the transfer of responsibility for the performance of an activity to another individual while retaining accountability for the outcome. Used appropriately, delegation can result in safe and effective nursing care and contribute to improved patient care outcomes (Barrow & Sharma, 2021). Delegation allows the registered nurse (RN) to attend to more complex patient care needs, develops the skills of assistive personnel, and promotes cost containment for the health care organization (ANA & NCSBN, 2019). The decision to delegate is based upon the RN's judgment concerning the condition of the patient, the competence of all members of the nursing team, and the degree of supervision that will be required of the RN if a task is delegated (ANA & NCSBN, 2019).

In delegating, the RN must ensure appropriate assessment, planning, implementation, and evaluation. Decision making about delegation is a continuous process. These guidelines provide a quick reference for the delegation decision-making information found in each skill.

DELEGATION CRITERIA

Criteria to be considered by the RN when deciding to delegate care activities (ANA & NCSBN, 2019) include:

. The State Nursing Practice Act must permit delegation and outline the authorized task(s) to be delegated or authorize the RN to decide delegation.
. The person delegating has the appropriate qualifications: appropriate education, skills, and experience as well as current competency.
. The person receiving the delegation must have the appropriate qualifications: appropriate education, training, skills, and experience as well as evidence of current competency.

In addition, according to the ANA and NCSBN (2019), the delegated task(s) must not involve critical decision making or nursing judgment.

DELEGATION PROCESS

Delegation is a multistep, continuous process.

. The RN must be fully aware of the parameters for delegation as outlined in their state's Nurse Practice Act as well as the employing organization's policies and procedures regarding delegation (Daley, 2013).
. The RN must assess the situation, identifying the needs of the patient, considering the circumstances and setting, as well as the competence of the person to whom the task is being delegated (delegatee). The RN may proceed with delegation if patient needs, circumstances, and available resources indicate patient safety will be maintained with delegated care.
. The RN plans for and clearly communicates the specific task(s) to be delegated. The RN may proceed with delegation if the nature of the task, competence of the person receiving the delegation, and patient implications indicate patient safety will be maintained with delegated care.
. The RN maintains overall accountability for the patient. The delegatee bears the responsibility for the delegated activity, skill, or procedure (ANA & NCSBN, 2019). The RN may proceed with delegation if the RN and person receiving the delegation accept the accountability for their respective roles in the delegated patient care.
. The RN supervises performance of the delegated task(s), providing directions and clear expectations of how the task(s) is to be performed. The RN monitors performance, intervenes if necessary, and ensures the appropriate documentation.
. The RN must evaluate the entire delegation process, evaluating the patient, the performance of the task(s), and obtain and provide feedback.
. The RN must reassess and adjust the overall plan of care, as needed.

FIVE RIGHTS OF DELEGATION

The Five Rights of Delegation provide a resource to facilitate decisions about delegation. The ANA and NCSBN (2019) identify the Five Rights of Delegation as follows:

- **Right Task:** One that falls within the delegatee's job description or is included as part of the established written policies and procedures of the practice setting.

- **Right Circumstances:** The health condition of the patient must be stable. Changes in the patient's condition require the delegatee to communicate this to the RN, and the RN must reassess the situation and the appropriateness of the delegation.
- **Right Person:** The delegatee possesses the appropriate skills and knowledge to perform the activity.
- **Right Direction/Communication:** Each delegation situation should be specific to the patient, the licensed nurse, and the delegatee. A clear, concise description of the task, including its objective, limits, and expectations should be provided.
- **Right Supervision/Evaluation:** This includes appropriate monitoring, evaluation, intervention, as needed, and feedback.

"DO-NOT-DELEGATE" CARE

Nursing care or tasks that should never be delegated except to another RN include:

- Initial and ongoing nursing assessment of the patient and their nursing care needs
- Determination of the nursing diagnosis, nursing care plan, evaluation of the patient's progress in relation to the care plan, and evaluation of the nursing care delivered to the patient
- Supervision and education of nursing personnel; patient teaching that requires an assessment of the patient and their education needs
- Any other nursing interventions that require professional nursing knowledge, judgment, and/or skill

DELEGATION DECISION TREE

Using skills, knowledge, and professional judgment, the RN determines appropriate nursing practice based on the state practice act and professional scope of practice, the standards and code of ethics, and the organization's policies and procedures related to delegation (ANA & NCSBN, 2019).

The Decision Tree for Delegation by Registered Nurses distributed by the American Nurses Association and the National Council of State Boards of Nursing can assist nurses with delegation decisions. The Decision Tree for Delegation can be found at https://www.ncsbn.org/Delegation_joint_statement_NCSBN-ANA.pdf

APPENDIX B
EQUIVALENTS

METRIC UNITS

The metric system, developed by the French, uses the *meter* as the basic unit. The metric system is a decimal system, with prefixes that designate the various multiples or divisibles of 10. The most commonly used prefixes in health care are:

Milli-, which means one one-thousandth (0.001)
Centi-, which means one one-hundredth (0.01)
Kilo-, which means one thousand (1,000)

These prefixes may be affixed to any of the three basic units of measurements, which are:

Meter (m), the unit of length
Gram (g), the unit of weight
Liter (L), the unit of volume

Therefore,

1 millimeter (mm) = 0.001 m
1 milligram (mg) = 0.001 g
1 milliliter (mL) = 0.001 L
1 kilometer (km) = 1,000 m
1 kilogram (kg) = 1,000 g
1 kiloliter (kL) = 1,000 L

Length

The meter (a little longer than a yard) and the kilometer (about 0.6 mile) seldom are used in health care. The commonly used measure of length is 1 centimeter (cm) = 0.01 m = about 0.4 inch (in). There are 2.54 cm in 1 in.

Volume

The most frequently used measures of volume are the *liter* and the *milliliter*. A useful equivalent to know is: 1,000 mL = 1 L. The term *cc*, which stands for cubic centimeter, should not be used in written documentation. It is still used verbally by some practitioners, but mL is the preferred measure of volume. 1 mL = 1 cc.

Weight

The gram designates the weight of 1 mL of distilled water at 4°C. The most frequently used units of weight are:

1,000,000 micrograms (mcg) = 1 gram (g)
1,000 micrograms (mcg) = 1 milligram (mg)
1,000 milligrams (mg) = 1 gram (g)
1,000 grams (g) = 1 kilogram (kg) = 2.2 pounds (lb)

METRIC UNITS AND THEIR HOUSEHOLD EQUIVALENTS

The household system is not widely used except in some community settings, such as a person's home. The household system is not as accurate as the metric system because of the lack of standardization of spoons and cups. The measurements are approximate. Teaspoon and tablespoon refer to measuring spoons, not silverware. A teaspoon is considered to be equivalent to 60 drops (gtts). Three teaspoons equal one tablespoon. Metric and Household equivalents are outlined in Table B-1.

Table B-1 Metric and Household Equivalents

METRIC UNIT	HOUSEHOLD UNIT
5 mL	1 Tsp

15 mL	1 Tbsp
30 mL	2 Tbsp
30 mL	1 oz
240 mL	8 oz (1 full glass)
500 mL	1 pt
1,000 mL	1 qt

Note: There are many discrepancies among these approximate equivalents. For example, 30 mL is the accepted equivalent for 1 oz (29.57 mL is the exact equivalent). Such discrepancies are inevitable when two systems are used whose equivalents are not exact. If the discrepancies are within a 10% margin of error, they usually are acceptable in pharmacology.

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

APPENDIX C
Adult Laboratory Values*

Commonly Used Abbreviations

kg = kilogram
g = gram
mg = milligram
mcg = microgram
mEq = milliequivalent
L = liter
dL (deciliter) = 100 milliliters
mL = milliliter
mIU = milli-International Unit
mm = millimeter
mm Hg = millimeters of mercury
IU = International Unit

*Laboratory values may vary according to techniques used in different laboratories.

Table C-1 Hematologic Values—Reference Ranges

Determination	Conventional Unit	Reference Range, SI
Coagulation Factors		
Factor I (fibrinogen)	0.15–0.35 g/dL	4.0–10.0 mcmol/L
Factor II (prothrombin)	60–140%	0.60–1.40 mcmol/L
Factor V (accelerator globulin)	60–140%	0.60–1.40 mcmol/L
Factors VII to X (proconvertin to Stuart factor)	70–130%	0.70–1.30 mcmol/L
Factor X (Stuart factor)	60–140%	0.70–1.30 mcmol/L
Factor VIII (antihemophilic globulin)	50–200%	0.50–2.0 mcmol/L
Factor IX (plasma thromboplastic cofactor)	60–140%	0.60–1.40 mcmol/L
Factor XI (plasma thromboplastic antecedent)	60–140%	0.60–1.40 mcmol/L
Factor XII (Hageman factor)	60–140%	0.60–1.40 mcmol/L
Coagulation Screening Tests		
Bleeding time (Simplate)	2–8 min	180–540 sec
Prothrombin time	9.5–12 sec	Less than 2 sec from control
Partial thromboplastin time (activated)	20–45 sec	25–37 sec
INR	1.0	None
Whole blood clot lysis	No clot lysis in 24 hr	0/day
Fibrinolytic Studies		
Euglobin lysis	No lysis in 2 hr	0 (in 2 hr)
Thrombin time		Control 15 sec

Complete Blood Count		
Hematocrit	Male: 42–50% Female: 40–48%	Male: 0.42–0.52 Female: 0.37–0.48
Hemoglobin	Male: 13–18 g/dL Female: 12–16 g/dL	Male: 8.1–11.2 mmol/L Female: 7.4–9.9 mmol/L
Leukocyte count	5,000–10,000/mm^3	4.3–10.8 × 10^9/L
Erythrocyte count	4.2 million–5.9 million/mm^3	4.2–5.9 × 10^{12}/L
Mean corpuscular volume (MCV)	80–94 mcm^3	80–94 fl
Mean corpuscular hemoglobin (MCH)	27–32 pg	1.7–2.0 fmol
Mean corpuscular hemoglobin concentration (MCHC)	33–38%	19–22.8 mmol/L
Erythrocyte sedimentation rate (Zeta Centrifuge)	41–54%	Male: 1–13 mm/h Female: 1–20 mm/h
Erythrocyte Enzymes		
Glucose-6-phosphate dehydrogenase	5–15 U/g Hb	5–15 U/g
Pyruvate kinase	13–17 U/g Hb	13–17 U/g
Ferritin (serum)	Females: 5–100 ng/mL Males: 10–270 ng/mL	
Folic acid, RIA	4–16 ng/mL	
Haptoglobin	50–250 mg/dL	1.0 g–3.0 g/L
Hemoglobin Studies		
Electrophoresis for A_2 hemoglobin	1.5–3.5%	0.015–0.035
Hemoglobin, met- and sulf-	0	0
Serum hemoglobin	2–3 mg/100 mL	1.2–1.9 mcmol/L
Lupus erythematosus (LE) preparation		
Heparin as anticoagulant	0	0
Defibrinated blood	0	0
Muramidase	Serum, 3–7 mcg/mL Urine, 0–2 mcg/mL	3–7 mg/L 0–2 mg/L
Osmotic fragility of erythrocyte	Increased if hemolysis occurs in over 0.5% NaCl; decreased if hemolysis is incomplete in 0.3% NaCl	
Peroxide hemolysis	<10%	<0.10
Platelet count	100,000–400,000/mm^3	150–350 × 10^9/L
Platelet Function Tests		
Clot retraction	50–100%/2 hr	0.50–1.00/2 hr
Platelet aggregation	Full response to ADP, epinephrine and collagen	1.0

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Platelet factor 3	33–57 sec	33–57 sec
Reticulocyte count	0.5–1.5% red cells	0.005–0.15
Vitamin B_{12}	90–280 pg/mL (borderline: 70–90)	66–207 pmol/L (borderline: 52–66)

Table C-2 Blood, Plasma, or Serum Values—Reference Ranges

Determination	Conventional	SI
Acetoacetate plus acetone	0.3–2.0 mg/dL	3–20 mg/L
Aldolase	1.3–8.2 mU/mL	12–75 nmol sec^{-1}/L
Alpha amino nitrogen	3.0–5.5 mg/100 mL	2.1–3.9 mmol/L
Ammonia	80–110 mcg/100 mL	47–65 mcmol/L
Ascorbic acid	0.4–1.5 mg/100 mL	23–85 mcmol/L
Bilirubin (van den Bergh test)	1 min: 0.4 mg/100 mL Direct: 0.1–0.2 mg/dL Total: 1.0 mg/100 mL Indirect: 0.1–1.0 mg/dL	Up to 7 mcmol/L Up to 17 mcmol/L
Blood volume	8.5–9.0% of body weight in kg Toxic level: 17 mEq/L	80–85 mL/kg
Bromsulphalein (BSP)	<5% retention 45 min after 5 mg/kg IV	<0.05 L
Calcium	8.5–10.5 mg/100 mL	2.1–2.5 mmol/L
Carbon dioxide content	24 mEq–32 mEq/L	24–30 mmol/L
Carcinoembryonic antigen (CEA)	0.25 mg/mL	0–2.5 mcg/L
Carotenoids	0.8–4.0 mcg/mL	1.5–7.4 mcmol/L
Ceruloplasmin	27–37 mg/100 mL	1.8–2.4 mcmol/L
Chloride	95–105 mEq/L	100–106 mmol/L
Cholesterol	<200 mg/dL	
Cholinesterase (pseudocholinesterase)	0.5 pH U or more/hr 0.7 pH U or more/hr for packed cells	0.5 arb unit or more
Copper	Total: 100–200 mcg/100 mL	16–31 mcmol/L
Creatine phosphokinase (CPK)	Female: 50–250 mU/mL Male: 50–325 mU/mL	0.08–0.58 mcmol sec^{-1}/L
Creatinine	0.7–1.4 mg/100 mL	60–130 mcmol/L
Ethanol	0.3–0.4%, marked intoxication 0.4–0.5%, alcoholic stupor ≥0.5%, alcoholic coma	65–87 mmol/L 87–109 mmol/L >109 mmol/L
Glucose	Fasting: 60–100 mg/dL	3.9–5.6 mmol/L
Glycated hemoglobin (HbA1c)	4.0–5.6%	None
Iron	65–170 mcg/100 mL (higher in males)	9.0–26.9 mcmol/L
Iron-binding capacity	250–410 mcg/100 mL	44.8–73.4 mcmol/L
Lactic acid	0.6–1.8 mEq/L	0.6–1.8 mmol/L
Lactic dehydrogenase isoenzymes	100–225 mU/mL	1.00–2.00 mcmol sec^{-1}/L
Lead	≤50 mcg/100 mL	Up to 2.4 mcmol/L
Lipase	≤2 U/mL	Up to 2 arb units

Lipids, total	400–1,000 mg/dL	3.10–5.69 mmol/L
Magnesium	0.33–2.4 mEq/L	0.8–1.3 mmol/L
5^9 Nucleotidase	0.3–3.2 Bodansky U	30–290 nmol sec^{-1}/L
Osmolality	280–300 mOsm/kg water	285–295 mmol/kg
Oxygen saturation (arterial)	95–100%	0.96–1.00 L
P_{CO_2}	35–45 mm Hg	4.7–6.0 kPg
pH	7.35–7.45	Same
P_{o_2}	95–100 mm Hg (dependent on age while breathing room air) >500 mm Hg while on 100% O_2	10.0–13.3 kPa
Phenylalanine	0–2 mg/100 mL	0–120 mcmol/L
Phosphorus (inorganic)	3.0–4.5 mg/100 mL	1.0–1.5 mmol/L
Potassium	3.8–5.0 mEq/L	3.5–5.0 mmol/L
Primidone (Mysoline)	Therapeutic level, 4–12 mcg/mL	18–55 mcmol/L
Protein, total	6.0–8.0 g/100 mL	60–84 g/L
Albumin	3.5–5.0 g/100 mL	33–50 g/L
Globulin	1.5–3.0 g/100 mL	23–35 g/L
Electrophoresis	% of total protein	% of total protein
Albumin	3.3–5.0 g/dL	0.52–0.68
Globulin		
$Alpha_1$	0.2–0.4 g/dL	0.042–0.072
$Alpha_2$	0.6–1.0 g/dL	0.068–0.12
Beta	0.6–1.2 g/dL	0.093–0.15
Gamma	0.7–1.5 g/dL 0.3–0.7 mg/dL	0.13–0.23 0–0.11 mmol/L
Sodium	135–145 mEq/L	135–145 mmol/L
Sulfate	0.5–1.5 mg/100 mL	0.05–1.2 mmol/L
Transaminase (SGOT) (aspartate aminotransferase)	7–40 U/mL	0.08–0.32 mcmol sec^{-1}/L
Urea nitrogen (BUN)	10–20 mg/100 mL	2.9–8.9 mmol/L
Uric acid	2.5–8.0 mg/100 mL	0.13–0.42 mmol/L
Vitamin A	50–220 mcg/dL	0.5–2.1 mcmol/L

Table C-3 Urine Values—Reference Ranges

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

DETERMINATION	CONVENTIONAL	SI
Acetone plus acetoacetate (quantitative)	0	0 mg/L
Alpha amino nitrogen	64–199 mg/day; not over 1.5% of total nitrogen	4.6–14.2 mmol/day
Amylase	35–260 U/mL	24–76 arb units
Calcium	150 mg/day or less	3.8 mmol/day or less
Catecholamines	Epinephrine, 10–40% Norepinephrine, 60–90%	<55 nmol/day <590 nmol/day
Copper	20–70 mcg/day	0–1.6 mcmol/day
Coproporphyrin	50–300 mcg/day	80–380 nmol/day
Creatine	0–200 mg/24 hr	<0.75 mmol/day
Cystine or cysteine	0	0
Follicle-stimulating hormone		
Follicular phase	5–20 IU/day	Same
Midcycle	15–60 IU/day	
Luteal phase	5–15 IU/day	
Menopausal	50–100 IU/day	
Men	5–25 IU/day	
Hemoglobin and myoglobin	0	
5-Hydroxyindole acetic acid	2–9 mg/day (women lower than men)	10–45 mcmol/day
Phenolsulfonphthalein (PSP)	At least 25% excreted by 15 min; 40% by 30 min; 60% by 120 min	0.25 L
Phosphorus (inorganic)	Varies with intake; average 1 g/day	32 mmol/day
Porphobilinogen	0	0
Protein, quantitative	<150 mg/24 hr	<0.15 g/day
Steroids		
17-Ketosteroids (per day)	Age (yr) / Male (mg) / Female (mg)	Male (mcmol/day) / Female (mcmol/day)
	10 / 1–4 / 1–4	3–14 / 3–14
	20 / 6–21 / 4–16	21–73 / 14–56
	30 / 8–26 / 4–14	28–90 / 14–49
	50 / 5–18 / 3–9	17–62 / 10–31
	70 / 2–10 / 1–7	7–35 / 3–24
17-Hydroxysteroids	3–8 mg/day (women lower than men)	8–22 mcmol/day as hydrocortisone
Sugar		
Quantitative glucose	0	0 mmol/L
Identification of reducing substances		
Fructose	0	0 mmol/L
Pentose	0	0 mmol/L
Titratable acidity	20–40 mEq/day	20–40 mmol/day
Urobilinogen	<0.25 mg/dL	To 1.0 arb unit
Uroporphyrin	Up to 50 mcg in 24 hr	0 nmol/day
Vanillylmandelic acid (VMA)	0.7–6.8 mg/24 hr	Up to 45 mcmol/day

Table C-4 Cerebrospinal Fluid Values—Reference Ranges

Determination	Conventional	SI
Bilirubin	0	0 mcmol/L
Chloride	100–130 mEq/L	
Albumin	15.5–32.0 mg/dL	0.295 g/L 6 2 SD (0.11–0.48)
IgG	0–6.6 mg/dL	0.043 g/L 6 2 SD (0–0.086)

Glucose	50–75 mg/100 mL (30–50% less than blood)	2.8–4.2 mmol/L
Pressure (initial)	70–180 mm H_2O	70–80 arb units
Protein Lumbar Cisternal Ventricular	15–45 mg/100 mL 15–25 mg/100 mL 5–15 mg/100 mL	0.15–0.45 g/L 0.15–0.25 g/L 0.05–0.15 g/L

Table C-5 Special Endocrine Tests—Reference Ranges

Determination	Conventional	SI
Steroid Hormones		
Aldosterone Fasting, at rest, 210 mEq sodium diet Fasting, at rest, 110 mEq sodium diet Fasting, at rest, 10 mEq sodium diet	Excretion: 5–19 mcg/24 hr Supine: 48 ± 29 pg/mL Upright: (2 h) 65 ± 23 pg/mL Supine: 107 ± 45 pg/mL Upright: 239 ± 123 pg/mL Supine: 175 ± 75 pg/mL Upright: 532 ± 228 pg/mL	14–53 nmol/day 133 ± 80 pmol/L 180 ± 64 pmol/L 279 ± 125 pmol/L 663 ± 341 pmol/L 485 ± 208 pmol/L 1,476 ± 632 pmol/L
Cortisol Fasting At rest 20 U ACTH	8 AM: 5–25 mcg/100 mL 8 PM: <10 mcg/100 mL 4-hour ACTH test: 30–45 mcg/100 mL	0.14–0.69 mcmol/L 0–0.28 mcmol/L 0.83–1.24 mcmol/L
Dexamethasone at midnight	Overnight suppression test: <5 mcg/100 mL Excretion: 20–70 mcg/24 hr	<0.14 nmol/L 55–193 nmol/day
11-Deoxycortisol	Responsive: >7.5 mcg/100 mL (after metrapone)	>0.22 mcmol/L
Testosterone	Adult male: 300–1,100 ng/100 mL Adolescent male: >100 ng/100 mL Females: 25–90 ng/100 mL	10.4–38.1 nmol/L >3.5 nmol/L 0.87–3.12 nmol/L
Unbound testosterone	Adult male: 3.06–24.0 ng/100 mL Adult female: 0.09–1.28 ng/100 mL	106–832 pmol/L 3.1–44.4 pmol/L
Polypeptide Hormones		
Adrenocorticotrophin (ACTH)	15–70 pg/mL	3.3–15.4 pmol/L
Calcitonin	Undetectable in normals >100 pg/mL in medullary carcinoma	0 >29.3 pmol/L
Growth hormone Fasting, at rest After exercise After glucose	<5 ng/mL Children: >10 ng/mL Male: <5 ng/mL Female: up to 30 ng/mL Male: <5 ng/mL Female: <10 mg/mL	<233 pmol/L >465 pmol/L <233 pmol/L 0–1,395 pmol/L 0–233 pmol/L 0–465 pmol/L
Insulin Fasting During hypoglycemia After glucose	6–26 mcU/mL 20 mcU/mL Up to 150 mcU/mL	43–187 pmol/L <144 pmol/L 0–1,078 pmol/L
Luteinizing hormone Preovulatory or postovulatory Midcycle peak	Male: 6–18 mU/mL Female: 5–22 mU/mL 30–250 mU/mL	6–18 U/L 5–22 U/L 30–250 U/L
Parathyroid hormone	<10 mcl equiv/mL	<10 mL equiv/L
Prolactin	2–15 ng/mL	0.08–6.0 nmol/L

for more ebook/ testbank/ solution manuals requests: email 960126734@qq.com

Renin activity Normal diet Low-sodium diet High-sodium diet	Supine: 1.1 ± 0.8 ng/mL/hr Upright: 1.9 ± 1.7 ng/mL/hr Supine: 2.7 ± 1.8 ng/mL/hr Upright: 6.6 ± 2.5 ng/mL/hr Diuretics: 10.0 ± 3.7 ng/mL/hr	0.9 ± 0.6 nmol/L/hr 1.5 ± 1.3 nmol/L/hr 2.1 ± 1.4 nmol/L/hr 5.1 ± 1.9 nmol/L/hr 7.7 ± 2.9 nmol/L/hr
Thyroid Hormones		
Thyroid-stimulating hormone (TSH)	0.5–3.5 mcU/mL	0.5–3.5 mU/L
Thyroxine-binding globulin capacity	15–25 mcg T_4/100 mL	193–322 mU/L
Total triiodothyronine by radioimmunoassay (RIA; T_3)	70–190 ng/100 mL	1.08–2.92 nmol/L
Total thyroxine (T_4) by RIA	4–12 mcg/100 mL	52–154 nmol/L
T_3 resin uptake	25–35%	0.25–0.35
Free thyroxine index (FT_4I)	1–4 ng/100 mL	12.8–51.2 pmol/L
